**Tip:** Use \lo_list to find out the large object’s OID.

\o or \out [ filename ]
\o or \out [ |command ]

Arranges to save future query results to the file filename or pipe future results to the shell command command. If no argument is specified, the query output is reset to the standard output.

“Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as \d), but not error messages.

**Tip:** To intersperse text output in between query results, use \qecho.

\p or \print

Print the current query buffer to the standard output.

\password [ username ]

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an ALTER ROLE command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [ text ] name

Prompts the user to supply text, which is assigned to the variable name. An optional prompt string, text, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, \prompt uses the terminal for input and output. However, if the -f command line switch was used, \prompt uses standard input and standard output.

\pset [ option [ value ] ]

This command sets options affecting the output of query result tables. option indicates which option is to be set. The semantics of value vary depending on the selected option. For some options, omitting value causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting value just results in the current setting being displayed.

\pset without any arguments displays the current status of all printing options.

Adjustable printing options are:

**border**

The value must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the border=... attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the
same as `border = 2`. The `latex` and `latex-longtable` formats additionally allow a value of 3 to add dividing lines between data rows.

**columns**

Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the `wrapped` format only affects screen output. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

**expanded (or x)**

If `value` is specified it must be either `on` or `off`, which will enable or disable expanded mode, or `auto`. If `value` is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal “horizontal” mode. In the auto setting, the expanded mode is used whenever the query output is wider than the screen, otherwise the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

**fieldsep**

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep ’	’`. The default field separator is ’|’ (a vertical bar).

**fieldsep_zero**

Sets the field separator to use in unaligned output format to a zero byte.

**footer**

If `value` is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If `value` is omitted the command toggles footer display on or off.

**format**

Sets the output format to one of `unaligned`, `aligned`, `wrapped`, `html`, `asciidoc`, `latex (uses tabular)`, `latex-longtable`, or `troff-ms`. Unique abbreviations are allowed.

- **unaligned** format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).
- **aligned** format is the standard, human-readable, nicely formatted text output; this is the default.
- **wrapped** format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.
The html, asciidoc, latex, latex-longtable, and troff-ms formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. latex-longtable also requires the LaTeX longtable and booktabs packages.

**linestyle**

Sets the border line drawing style to one of ascii, old-ascii or unicode. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is ascii. This option only affects the aligned and wrapped output formats.

- **ascii** style uses plain ASCII characters. Newlines in data are shown using a + symbol in the right-hand margin. When the wrapped format wraps data from one line to the next without a newline character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

- **old-ascii** style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a : symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a ; symbol is used in place of the left-hand column separator.

- **unicode** style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the border setting is greater than zero, the linestyle option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

**null**

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer \pset null '(null)'.

**numericlocale**

If value is specified it must be either on or off which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.

**pager**

Controls use of a pager program for query and psql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used.

When the pager option is off, the pager program is not used. When the pager option is on, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The pager option can also be set to always, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. \pset pager without a value toggles pager use on and off.
pager_min_lines

If `pager_min_lines` is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

recordsep

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

recordsep_zero

Sets the record separator to use in unaligned output format to a zero byte.

tableattr (or `T`)

In HTML format, this specifies attributes to be placed inside the `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don’t want to specify `border` here, as that is already taken care of by \pset `border`. If no value is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g. ‘0.2 0.2 0.6’. Unspecified output columns use the last specified value.

title

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title is unset.

tuples_only (or `t`)

If value is specified it must be either on or off which will enable or disable tuples-only mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.

unicode_border_linestyle

Sets the border drawing style for the `unicode` line style to one of single or double.

unicode_column_linestyle

Sets the column drawing style for the `unicode` line style to one of single or double.

unicode_header_linestyle

Sets the header drawing style for the `unicode` line style to one of single or double.

Illustrations of how these different formats look can be seen in the `Examples` section.

**Tip:** There are various shortcut commands for \pset. See \a, \c, \f, \h, \t, \T, and \x.

\q or \quit

Quits the psql program. In a script file, only execution of that script is terminated.
This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r` or `\reset`

Resets (clears) the query buffer.

`\s` `[ filename ]`

Print psql’s command line history to `filename`. If `filename` is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

`\set` `[ name [ value [ ... ] ] ]`

Sets the psql variable `name` to `value`, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set with an empty value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See the section `Variables` below for details. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, psql treats several variables as special. They are documented in the section about variables.

**Note:** This command is unrelated to the SQL command SET.

`\setenv` `name` `[ value ]`

Sets the environment variable `name` to `value`, or if the `value` is not supplied, unsets the environment variable. Example:

```
testdb> \setenv PAGER less
testdb> \setenv LESS -imx4F
```

`\sf` `+` `function_description`

This command fetches and shows the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

`\t`

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.
\T table_options

Specifies attributes to be placed within the table tag in HTML output format. This command is equivalent to \pset tableattr table_options.

\timing [ on | off ]

Without parameter, toggles a display of how long each SQL statement takes, in milliseconds. With parameter, sets same.

\unset name

Unsets (deletes) the psql variable name.

\w or \write filename
\w or \write | command

Outputs the current query buffer to the file filename or pipes it to the shell command command.

\watch [ seconds ]

Repeatedly execute the current query buffer (like \g) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions.

\x [ on | off | auto ]

Sets or toggles expanded table formatting mode. As such it is equivalent to \pset expanded.

\z [ pattern ]

Lists tables, views and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed.

This is an alias for \dp ("display privileges").

\! [ command ]

Escapes to a separate shell or executes the shell command command. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

\? [ topic ]

Shows help information. The optional topic parameter (defaulting to commands) selects which part of psql is explained: commands describes psql’s backslash commands; options describes the command-line options that can be passed to psql; and variables shows help about psql configuration variables.

Patterns

The various \d commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, \dt FOO will display the table named foo. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, \dt "FOO""BAR" will display the table named FOO"BAR (not foo"bar). Unlike the normal rules for
SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Whenever the `pattern` parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path — this is equivalent to using `*` as the pattern. (An object is said to be `visible` if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use `*.*` as the pattern.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, `\dt int*` displays tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.*bar*` displays all tables whose table name includes `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example `[0-9]` to match any digit. All regular expression special characters work as specified in Section 9.7.3, except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, `?` which is translated to `.*`, and `$` which is matched literally. You can emulate these pattern characters at need by writing `?` for `.*`, `(R+|)` for `R*`, or `(R|)` for `R?.` $ is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, $ is automatically appended to your pattern). Write `*` at the beginning and/or end if you don’t wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of `\do`).

**Advanced Features**

**Variables**

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo bar
```

1926
This works in both regular SQL commands and meta-commands; there is more detail in *SQL Interpolation*, below.

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

**Note:** The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by `psql`. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of `psql`. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables’ names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

**AUTOCOMMIT**

When *on* (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION` SQL command. When *off* or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`.

The autocommit-off mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as `VACUUM`).

**Note:** In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

**Note:** The autocommit-on mode is PostgreSQL’s traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide `psqlrc` file or your `~/.psqlrc` file.

**COMP_KEYWORD_CASE**

Determines which letter case to use when completing an SQL key word. If set to *lower* or *upper*, the completed word will be in lower or upper case, respectively. If set to *preserve-lower* or *preserve-upper* (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.
**DBNAME**

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**ECHO**

If set to all, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch -a. If set to queries, psql prints each query to standard output as it is sent to the server. The switch for this is -e. If set to errors, then only failed queries are displayed on standard error output. The switch for this is -b. If unset, or if set to none (or any other value than those above) then no queries are displayed.

**ECHO_HIDDEN**

When this variable is set to on and a backslash command queries the database, the query is first shown. This feature helps you to study PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.) If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and executed.

**ENCODING**

The current client character set encoding.

**FETCH_COUNT**

If this variable is set to an integer value > 0, the results of SELECT queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

**Tip:** Although you can use any output format with this feature, the default aligned format tends to look bad because each group of FETCH_COUNT rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

**HISTCONTROL**

If this variable is set to ignorespace, lines which begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not entered. A value of ignoreboth combines the two options. If unset, or if set to none (or any other value than those above), all lines read in interactive mode are saved on the history list.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTFILE**

The file name that will be used to store the history list. The default value is ~/.psql_history. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
```
in ~/.psqlrc will cause psql to maintain a separate history for each database.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTSIZE**

The number of commands to store in the command history. The default value is 500.

**Note:** This feature was shamelessly plagiarized from Bash.

**HOST**

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**IGNOREEOF**

If unset, sending an EOF character (usually Control+D) to an interactive session of psql will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**Note:** This feature was shamelessly plagiarized from Bash.

**LASTOID**

The value of the last affected OID, as returned from an INSERT or \lo_import command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

**ON_ERROR_ROLLBACK**

When set to on, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to interactive, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to off, a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit SAVEPOINT for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

**ON_ERROR_STOP**

By default, command processing continues after an error. When this variable is set to on, processing will instead stop immediately. In interactive mode, psql will return to the command prompt; otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have in invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.
PORT

The database server port to which you are currently connected. This is set every time you connect to
a database (including program start-up), but can be unset.

PROMPT1
PROMPT2
PROMPT3

These specify what the prompts psql issues should look like. See Promting below.

QUIET

Setting this variable to on is equivalent to the command line option -q. It is probably not too useful
in interactive mode.

SINGLELINE

Setting this variable to on is equivalent to the command line option -S.

SINGLESTEP

Setting this variable to on is equivalent to the command line option -s.

USER

The database user you are currently connected as. This is set every time you connect to a database
(including program start-up), but can be unset.

VERBOSITY

This variable can be set to the values default, verbose, or terse to control the verbosity of error
reports.

SQL Interpolation

A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements,
as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that vari-
able values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value
without any quoting is to prepend the variable name with a colon (:). For example,

```
$testdb=
$testdb=> \set foo 'my_table'
$testdb=> SELECT * FROM :foo;
```

would query the table my_table. Note that this may be unsafe: the value of the variable is copied literally,
so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense
where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote
the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To
quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These
constructs deal correctly with quotes and other special characters embedded within the variable value. The
previous example would be more safely written this way:

```
$testdb=> \set foo 'my_table'
$testdb=> SELECT * FROM :"foo";
```
Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as ‘:foo’ doesn’t work to produce a quoted literal from a variable’s value (and it would be unsafe if it did work, since it wouldn’t correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable’s value as a quoted string:

```sql
testdb=> \set content 'cat my_file.txt'
testdb=> INSERT INTO my_table VALUES (:‘content’);
```

(Note that this still won’t work if `my_file.txt` contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, :name, :'name', or :"name") is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are PostgreSQL extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable’s value as an SQL literal or identifier is a psql extension.

**Prompting**

The prompts psql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when psql requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL COPY FROM STDIN command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

```
%M
The full host name (with domain name) of the database server, or [local] if the connection is over a Unix domain socket, or [local:/dir/name], if the Unix domain socket is not at the compiled in default location.

%m
The host name of the database server, truncated at the first dot, or [local] if the connection is over a Unix domain socket.

%>
The port number at which the database server is listening.

%n
The database session user name. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)
```
The name of the current database.

Like %/, but the output is ~ (tilde) if the database is your default database.

If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)

In prompt 1 normally =, but ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 %R is replaced by a character that depends on why psql expects more input: = if the command simply wasn’t terminated yet, but * if there is an unfinished /* ... */ comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 %R doesn’t produce anything.

Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

The line number inside the current statement, starting from 1.

The character with the indicated octal code is substituted.

The value of the psql variable name. See the section Variables for details.

The output of command, similar to ordinary “back-tick” substitution.

Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these can occur within the prompt. For example:

testdb=> \set PROMPT1 '%[\033[1;33;40m%\n8%/R%[\033[0m]%# ' results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

To insert a percent sign into your prompt, write %%.

Note: This feature was shamelessly plagiarized from tcsh.
Command-Line Editing

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. SET TRANSACTION ISOLATION LEVEL. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named .inputrc in your home directory:

```
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

Environment

COLUMNS

If \pset columns is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are more or less. The default is platform-dependent. Use of the pager can be disabled by setting PAGER to empty, or by using pager-related options of the \pset command.

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters (see Section 31.14).

PSQL_EDITOR
EDITOR
VISUAL

Editor used by the \e and \ef commands. The variables are examined in the order listed; the first that is set is used.

The built-in default editors are vi on Unix systems and notepad.exe on Windows systems.

PSQL_EDITOR_LINENUMBER_ARG

When \e or \ef is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or
vi, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'  # example for Unix-like systems
PSQL_EDITOR_LINENUMBER_ARG='--line '  # example for Windows
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

**PSQL_HISTORY**

Alternative location for the command history file. Tilde (~) expansion is performed.

**PSQLRC**

Alternative location of the user’s `.psqlrc` file. Tilde (~) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

**Files**

**psqlrc and ~/.psqlrc**

Unless it is passed an `-X` or `-c` option, `psql` attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user’s personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation’s “system configuration” directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `./etc/` relative to the directory containing the PostgreSQL executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user’s personal startup file is named `.psqlrc` and is sought in the invoking user’s home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user’s startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user’s personal startup file can be made `psql-version-specific` by appending a dash and the PostgreSQL major or minor release number to the file name, for example `~/.psqlrc-9.2` or `~/.psqlrc-9.2.5`. The most specific version-matching file will be read in preference to a non-version-specific file.

**.psql_history**

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.
The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

**Notes**

- In an earlier life psql allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. As of PostgreSQL 8.4 this is no longer allowed.

- psql works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than psql itself. However, backslash commands of the `\d` family should work with servers of versions back to 7.4, though not necessarily with servers newer than psql itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use psql to connect to several servers of different major versions, it is recommended that you use the newest version of psql. Alternatively, you can keep a copy of psql from each major version around and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

**Notes for Windows Users**

psql is built as a "console application". Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within psql. If psql detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

**Examples**

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
$ testdb=> CREATE TABLE my_table (  
  first integer not null default 0,  
  second text)  
$ testdb=> ;
CREATE TABLE
```

Now look at the table definition again:

```
$ testdb=> \d my_table
```

1935
Table "my_table"

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>integer</td>
<td>not null default 0</td>
</tr>
<tr>
<td>second</td>
<td>text</td>
<td></td>
</tr>
</tbody>
</table>

Now we change the prompt to something more interesting:

testdb=> \set PROMPT1 '%n@%m %~%R%# '
peter@localhost testdb=>

Let’s assume you have filled the table with data and want to take a look at it:

peter@localhost testdb=> SELECT * FROM my_table;
                      first | second
---------------------+--------
                    1 | one
                    2 | two
                    3 | three
                    4 | four
(4 rows)

You can display tables in different ways by using the \pset command:

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
+----------+
| first    | second  |
+----------+
 | 1 | one |
 | 2 | two |
 | 3 | three |
 | 4 | four |
(4 rows)

peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
 first | second
-------+--------
 1 | one
 2 | two
 3 | three
 4 | four
(4 rows)

peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ","
Field separator is ",".

1936
psql

peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;
one,1
two,2
three,3
four,4

Alternatively, use the short commands:

peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
- [ RECORD 1 ] -
  first | 1
  second | one
- [ RECORD 2 ] -
  first | 2
  second | two
- [ RECORD 3 ] -
  first | 3
  second | three
- [ RECORD 4 ] -
  first | 4
  second | four
reindexdb

Name

reindexdb — reindex a PostgreSQL database

Synopsis

reindexdb [connection-option...] [option...] [ --schema | -S schema ]... [ --table | -t table ]... [ --index | -i index ]... [dbname]

reindexdb [connection-option...] [option...] --all | -a

reindexdb [connection-option...] [option...] --system | -s [dbname]

Description

reindexdb is a utility for rebuilding indexes in a PostgreSQL database.

reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

Options

reindexdb accepts the following command-line arguments:

-a
--all

Reindex all databases.

[-d] dbname
[--dbname=] dbname

Specifies the name of the database to be reindexed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e
--echo

Echo the commands that reindexdb generates and sends to the server.

-i index
--index=index

Recreate index only. Multiple indexes can be recreated by writing multiple -i switches.
-q
--quiet
  Do not display progress messages.

-s
--system
  Reindex database’s system catalogs.

-S schema
--schema=schema
  Reindex schema only. Multiple schemas can be reindexed by writing multiple -S switches.

t table
--table=table
  Reindex table only. Multiple tables can be reindexed by writing multiple -t switches.

-v
--verbose
  Print detailed information during processing.

-V
--version
  Print the reindexdb version and exit.

-?
--help
  Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

-h host
--host=host
  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port
  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U username
--username=username
  User name to connect as.

-w
--no-password
  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

reindexdb

--password

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing --password to avoid the extra connection attempt.

--maintenance-db=dbname

Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the postgres database will be used, and if that does not exist, template1 will be used.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

Diagnostics

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

reindexdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 31.15 for more information.

Examples

To reindex the database test:

$ reindexdb test
To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
$ reindexdb --table foo --index bar abcd
```

**See Also**

REINDEX
vacuumdb

Name

vacuumdb — garbage-collect and analyze a PostgreSQL database

Synopsis

vacuumdb [connection-option...][option...][ --table|-t table [ ( column [ ... ] ) ] ... [dbname]]

vacuumdb [connection-option...][option...][--all|-a]

Description

cleanumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

cleanumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options

cleanumdb accepts the following command-line arguments:

-a
--all
  Vacuum all databases.

[-d] dbname
[--dbname=]dbname
  Specifies the name of the database to be cleaned or analyzed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

-e
--echo
  Echo the commands that vacuumdb generates and sends to the server.

-f
--full
  Perform “full” vacuuming.
vacuumdb

-\textbf{F} \hspace{1cm} --freeze

Aggressively “freeze” tuples.

-\textbf{j} \hspace{1cm} njobs \hspace{1cm} --jobs=njobs

Execute the vacuum or analyze commands in parallel by running \textit{njobs} commands simultaneously. This option reduces the time of the processing but it also increases the load on the database server. vacuumdb will open \textit{njobs} connections to the database, so make sure your max\_connections setting is high enough to accommodate all connections.

Note that using this mode together with the \textbf{--freeze} (FULL) option might cause deadlock failures if certain system catalogs are processed in parallel.

-\textbf{q} \hspace{1cm} --quiet

Do not display progress messages.

-\textbf{t} \hspace{1cm} table \hspace{1cm} \{ (column [, ...]) \} \hspace{1cm} --table=table \hspace{1cm} \{ (column [, ...]) \}

Clean or analyze \textit{table} only. Column names can be specified only in conjunction with the \textbf{--analyze} or \textbf{--analyze-only} options. Multiple tables can be vacuumed by writing multiple \textbf{-t} switches.

\textbf{Tip}: If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

-\textbf{v} \hspace{1cm} --verbose

Print detailed information during processing.

-\textbf{V} \hspace{1cm} --version

Print the vacuumdb version and exit.

-\textbf{z} \hspace{1cm} --analyze

Also calculate statistics for use by the optimizer.

-\textbf{Z} \hspace{1cm} --analyze-only

Only calculate statistics for use by the optimizer (no vacuum).

\textbf{--analyze-in-stages}

Only calculate statistics for use by the optimizer (no vacuum), like \textbf{--analyze-only}. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.
This option is useful to analyze a database that was newly populated from a restored dump or by `pg_upgrade`. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

```
-?
--help
```

Show help about vacuumdb command line arguments, and exit.

vacuumdb also accepts the following command-line arguments for connection parameters:

```
-h host
--host=host
```

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

```
-p port
--port=port
```

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force vacuumdb to prompt for a password before connecting to a database.

This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

```
--maintenance-db=dbname
```

Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.
Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

Diagnostics

In case of difficulty, see VACUUM and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

vacuumdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 31.15 for more information.

Examples

To clean the database test:

$ vacuumdb test

To clean and analyze for the optimizer a database named bigdb:

$ vacuumdb --analyze bigdb

To clean a single table foo in a database named xyzzy, and analyze a single column bar of the table for the optimizer:

$ vacuumdb --analyze --verbose --table 'foo(bar)' xyzzy

VACUUM
III. PostgreSQL Server Applications

This part contains reference information for PostgreSQL server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in Reference II, PostgreSQL Client Applications.
initdb

Name

initdb — create a new PostgreSQL database cluster

Synopsis

initdb [option...] [--pgdata | -D] directory

Description

initdb creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the template1 and postgres databases. When you later create a new database, everything in the template1 database is copied. (Therefore, anything installed in template1 is automatically copied into each database created later.) The postgres database is a default database meant for use by users, utilities and third party applications.

Although initdb will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use chown to assign ownership of that directory to the database user account, then su to become the database user to run initdb.

initdb must be run as the user that will own the server process, because the server needs to have access to the files and directories that initdb creates. Since the server cannot be run as root, you must not run initdb as root either. (It will in fact refuse to do so.)

initdb initializes the database cluster’s default locale and character set encoding. The character set encoding, collation order (LC_COLLATE) and character set classes (LC_CTYPE, e.g. upper, lower, digit) can be set separately for a database when it is created. initdb determines those settings for the template1 database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the --lc-collate and --lc-ctype options. Collation orders other than C or POSIX also have a performance penalty. For these reasons it is important to choose the right locale when running initdb.

The remaining locale categories can be changed later when the server is started. You can also use --locale to set the default for all locale categories, including collation order and character set classes. All server locale values (lc_*) can be displayed via SHOW ALL. More details can be found in Section 22.1.

To alter the default encoding, use the --encoding. More details can be found in Section 22.3.
Options

-A authmethod
--auth=authmethod

This option specifies the authentication method for local users used in pg_hba.conf (host and local lines). Do not use trust unless you trust all local users on your system. trust is the default for ease of installation.

--auth-host=authmethod

This option specifies the authentication method for local users via TCP/IP connections used in pg_hba.conf (host lines).

--auth-local=authmethod

This option specifies the authentication method for local users via Unix-domain socket connections used in pg_hba.conf (local lines).

-D directory
--pgdata=directory

This option specifies the directory where the database cluster should be stored. This is the only information required by initdb, but you can avoid writing it by setting the PGDATA environment variable, which can be convenient since the database server (postgres) can find the database directory later by the same variable.

-E encoding
--encoding=encoding

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or SQL_ASCII if that does not work. The character sets supported by the PostgreSQL server are described in Section 22.3.1.

-k
--data-checksums

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. This option can only be set during initialization, and cannot be changed later. If set, checksums are calculated for all objects, in all databases.

--locale=locale

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that initdb runs in. Locale support is described in Section 22.1.

--lc-collate=locale
--lc-type=locale
--lc-messages=locale
--lc-monetary=locale
--lc-numeric=locale
--lc-time=locale

Like --locale, but only sets the locale in the specified category.
--no-locale
   Equivalent to --locale=C.
-N
--nosync
   By default, initdb will wait for all files to be written safely to disk. This option causes initdb to
   return without waiting, which is faster, but means that a subsequent operating system crash can leave
   the data directory corrupt. Generally, this option is useful for testing, but should not be used when
   creating a production installation.
--pwfile=filename
   Makes initdb read the database superuser’s password from a file. The first line of the file is taken
   as the password.
-S
--sync-only
   Safely write all database files to disk and exit. This does not perform any of the normal initdb opera-
   tions.
-T CFG
--text-search-config=CFG
   Sets the default text search configuration. See default_text_search_config for further information.
-U username
--username=username
   Selects the user name of the database superuser. This defaults to the name of the effective user
   running initdb. It is really not important what the superuser’s name is, but one might choose to
   keep the customary name postgres, even if the operating system user’s name is different.
-W
--pwprompt
   Makes initdb prompt for a password to give the database superuser. If you don’t plan on using
   password authentication, this is not important. Otherwise you won’t be able to use password authen-
   tication until you have a password set up.
-X directory
--xlogdir=directory
   This option specifies the directory where the transaction log should be stored.

Other, less commonly used, options are also available:

-d
--debug
   Print debugging output from the bootstrap backend and a few other messages of lesser interest for
   the general public. The bootstrap backend is the program initdb uses to create the catalog tables.
   This option generates a tremendous amount of extremely boring output.
-L directory
   Specifies where initdb should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.

-n
--noclean
   By default, when initdb determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

-V
--version
   Print the initdb version and exit.

-?
--help
   Show help about initdb command line arguments, and exit.

Environment

PGDATA
   Specifies the directory where the database cluster is to be stored; can be overridden using the -D option.

TZ
   Specifies the default time zone of the created database cluster. The value should be a full time zone name (see Section 8.5.3).

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14).

Notes

initdb can also be invoked via pg_ctl initdb.

See Also

pg_ctl, postgres
pg_archivecleanup

Name

pg_archivecleanup — clean up PostgreSQL WAL archive files

Synopsis

pg_archivecleanup [option...] archivelocation oldestkeptwalfile

Description

pg_archivecleanup is designed to be used as an archive_cleanup_command to clean up WAL file archives when running as a standby server (see Section 25.2). pg_archivecleanup can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use pg_archivecleanup, put this into its recovery.conf configuration file:

archive_cleanup_command = 'pg_archivecleanup archivelocation %r'

where archivelocation is the directory from which WAL segment files should be removed.

When used within archive_cleanup_command, all WAL files logically preceding the value of the %r argument will be removed from archivelocation. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the archivelocation is a transient staging area for this particular standby server, but not when the archivelocation is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the oldestkeptwalfile will be removed from archivelocation. In this mode, if you specify a .partial or .backup file name, then only the file prefix will be used as the oldestkeptwalfile. This treatment of .backup file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name 000000010000003700000010:

pg_archivecleanup -d archive 000000010000003700000010.00000020.backup

pg_archivecleanup: keep WAL file "archive/000000010000003700000010" and later
pg_archivecleanup: removing file "archive/000000010000003700000000F"
pg_archivecleanup: removing file "archive/000000010000003700000000E"

pg_archivecleanup assumes that archivelocation is a directory readable and writable by the server-owning user.
Options

pg_archivecleanup accepts the following command-line arguments:

- **-d**
  Print lots of debug logging output on `stderr`.

- **-n**
  Print the names of the files that would have been removed on `stdout` (performs a dry run).

- **-V**
  `--version`
  Print the `pg_archivecleanup` version and exit.

- **-x extension**
  When using the program as a standalone utility, provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example: `-x .gz`.

- **-?**
  `--help`
  Show help about `pg_archivecleanup` command line arguments, and exit.

Notes

pg_archivecleanup is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

pg_archivecleanup is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs.

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory
See Also

pg_standby
pg_controldata

Name
pg_controldata — display control information of a PostgreSQL database cluster

Synopsis
pg_controldata [option][[-D] datadir]

Description
pg_controldata prints information initialized during initdb, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable PGDATA. This utility supports the options -V and --version, which print the pg_controldata version and exit. It also supports options --? and --help, which output the supported arguments.

Environment

PGDATA
   Default data directory location
**pg_ctl**

**Name**

*pg_ctl* — initialize, start, stop, or control a PostgreSQL server

**Synopsis**

```
pg_ctl init[db] [-s][.-D datadir][.-o initdb-options]
pg_ctl start [-w][-t seconds][-s][-D datadir][-l filename][-o options][-p path][-c]
pg_ctl stop [-W][-t seconds][-s][-D datadir][-m s[ mart] | f[ ast] | i[mmediate] ]
pg_ctl restart [-w][-t seconds][-s][-D datadir][-c][-m s[ mart] | f[ ast] | i[mmediate] ][-o options]
pg_ctl reload [-s][-D datadir]
pg_ctl status [-D datadir]
pg_ctl promote [-s][-D datadir]
pg_ctl kill signal_name process_id
pg_ctl register [-N servicename][-U username][-P password][-D datadir][-S a[uto] | d[emand] ][-w][-t seconds][-s][-o options]
pg_ctl unregister [-N servicename]
```

**Description**

*pg_ctl* is a utility for initializing a PostgreSQL database cluster, starting, stopping, or restarting the PostgreSQL database server (*postgres*), or displaying the status of a running server. Although the server can be started manually, *pg_ctl* encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The *init* or *initdb* mode creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance. This mode invokes the *initdb* command. See *initdb* for details.
In **start** mode, a new server is launched. The server is started in the background, and its standard input is attached to /dev/null (or nul on Windows). On Unix-like systems, by default, the server’s standard output and standard error are sent to pg_ctl’s standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like rotatelogs; otherwise postgres will write its output to the controlling terminal (from the background) and will not leave the shell’s process group. On Windows, by default the server’s standard output and standard error are sent to the terminal. These default behaviors can be changed by using --1 to append the server’s output to a log file. Use of either --1 or output redirection is recommended.

In **stop** mode, the server that is running in the specified data directory is shut down. Three different shutdown methods can be selected with the --m option. “Smart” mode waits for all active clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This will lead to a crash-recovery run on the next restart.

**restart** mode effectively executes a stop followed by a start. This allows changing the postgres command-line options. restart might fail if relative paths specified were specified on the command-line during server start.

**reload** mode simply sends the postgres process a SIGHUP signal, causing it to reread its configuration files (postgresql.conf, pg_hba.conf, etc.). This allows changing of configuration-file options that do not require a complete restart to take effect.

**status** mode checks whether a server is running in the specified data directory. If it is, the PID and the command line options that were used to invoke it are displayed. If the server is not running, the process returns an exit status of 3. If an accessible data directory is not specified, the process returns an exit status of 4.

In **promote** mode, the standby server that is running in the specified data directory is commanded to exit recovery and begin read-write operations.

**kill** mode allows you to send a signal to a specified process. This is particularly valuable for Microsoft Windows which does not have a kill command. Use --help to see a list of supported signal names.

**register** mode allows you to register a system service on Microsoft Windows. The --S option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

**unregister** mode allows you to unregister a system service on Microsoft Windows. This undoes the effects of the register command.

## Options

---

- **c**
- **--core-file**

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.
Specifies the file system location of the database configuration files. If this is omitted, the environment variable \texttt{PGDATA} is used.

Append the server log output to \texttt{filename}. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

Specifies the shutdown mode. \texttt{mode} can be \texttt{smart}, \texttt{fast}, or \texttt{immediate}, or the first letter of one of these three. If this is omitted, \texttt{fast} is used.

Specifies options to be passed directly to the \texttt{postgres} command; multiple option invocations are appended.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

Specifies options to be passed directly to the \texttt{initdb} command.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

Specifies the location of the \texttt{postgres} executable. By default the \texttt{postgres} executable is taken from the same directory as \texttt{pg_ctl}, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the \texttt{postgres} executable was not found.

In \texttt{init} mode, this option analogously specifies the location of the \texttt{initdb} executable.

Print only errors, no informational messages.

The maximum number of seconds to wait when waiting for startup or shutdown to complete. Defaults to the value of the \texttt{PGCTLTIMEOUT} environment variable or, if not set, to 60 seconds.

Print the \texttt{pg_ctl} version and exit.
pg_ctl

-\w
Wait for the startup or shutdown to complete. Waiting is the default option for shutdowns, but not startups. When waiting for startup, pg_ctl repeatedly attempts to connect to the server. When waiting for shutdown, pg_ctl waits for the server to remove its PID file. This option allows the entry of an SSL passphrase on startup. pg_ctl returns an exit code based on the success of the startup or shutdown.

-\W
Do not wait for startup or shutdown to complete. This is the default for start and restart modes.

-?  --help
Show help about pg_ctl command line arguments, and exit.

Options for Windows

-\e source
Name of the event source for pg_ctl to use for logging to the event log when running as a Windows service. The default is PostgreSQL. Note that this only controls the logging from pg_ctl itself; once started, the server will use the event source specified by event_source. Should the server fail during early startup, it might also log using the default event source PostgreSQL.

-\N servicename
Name of the system service to register. The name will be used as both the service name and the display name.

-\P password
Password for the user to start the service.

-\S start-type
Start type of the system service to register. start-type can be auto, or demand, or the first letter of one of these two. If this is omitted, auto is used.

-\U username
User name for the user to start the service. For domain users, use the format DOMAIN\username.

Environment

PGCTLTIMEOUT
Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA
Default data directory location.
pg_ctl, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 31.14). For additional server variables, see postgres.

**Files**

*postmaster.pid*

The existence of this file in the data directory is used to help `pg_ctl` determine if the server is currently running.

*postmaster.opts*

If this file exists in the data directory, `pg_ctl` (in `restart` mode) will pass the contents of the file as options to `postgres`, unless overridden by the `-o` option. The contents of this file are also displayed in `status` mode.

**Examples**

**Starting the Server**

To start the server:

```
$ pg_ctl start
```

To start the server, waiting until the server is accepting connections:

```
$ pg_ctl -w start
```

To start the server using port 5433, and running without `fsync`, use:

```
$ pg_ctl -o "-F -p 5433" start
```

**Stopping the Server**

To stop the server, use:

```
$ pg_ctl stop
```

The `-m` option allows control over how the server shuts down:

```
$ pg_ctl stop -m fast
```
Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that `pg_ctl` saves and reuses the command line options that were passed to the previously running instance. To restart the server in the simplest form, use:

```bash
$ pg_ctl restart
```

To restart the server, waiting for it to shut down and restart:

```bash
$ pg_ctl -w restart
```

To restart using port 5433, disabling `fsync` upon restart:

```bash
$ pg_ctl -o "-F -p 5433" restart
```

Showing the Server Status

Here is sample status output from `pg_ctl`:

```bash
$ pg_ctl status
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"
```

This is the command line that would be invoked in restart mode.

**Name**

`pg_resetxlog` — reset the write-ahead log and other control information of a PostgreSQL database cluster

**Synopsis**

```
```

**Description**

`pg_resetxlog` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetxlog` does not use the environment variable `PGDATA`.

If `pg_resetxlog` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting address fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. Do not execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

The `-o`, `-x`, `-e`, `-m`, `-O` and `-l` options allow the next OID, next transaction ID, next transaction ID’s epoch, next and oldest multitransaction ID, next multitransaction offset, oldest and newest transaction IDs for which the commit time can be retrieved, and WAL starting address values to be set manually. These are only needed when `pg_resetxlog` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as follows:

- A safe value for the next transaction ID (`-x`) can be determined by looking for the numerically largest file name in the directory `pg_clog` under the data directory, adding one, and then multiplying by 1048576. Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if `0011` is the largest entry in `pg_clog`, `-x 0x1200000` will work (five trailing zeroes provide the proper multiplier).
• A safe value for the next multitransaction ID (first part of -m) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536. Conversely, a safe value for the oldest multitransaction ID (second part of -m) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. As above, the file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.

• A safe value for the next multitransaction offset (-O) can be determined by looking for the numerically largest file name in the directory `pg_multixact/members` under the data directory, adding one, and then multiplying by 52352. As above, the file names are in hexadecimal. There is no simple recipe such as the ones above of appending zeroes.

• A safe value for the oldest transaction ID for which the commit time can be retrieved (first part of -c) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part of -c) can be determined by looking for the numerically greatest file name in the same directory. As above, the file names are in hexadecimal.

• The WAL starting address (-l) should be larger than any WAL segment file name currently existing in the directory `pg_xlog` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000001000000320000004A` is the largest entry in `pg_xlog`, use `-l 00000001000000320000004B` or higher.

  Note: `pg_resetxlog` itself looks at the files in `pg_xlog` and chooses a default -l setting beyond the last existing file name. Therefore, manual adjustment of -l should only be needed if you are aware of WAL segment files that are not currently present in `pg_xlog`, such as entries in an offline archive; or if the contents of `pg_xlog` have been lost entirely.

• There is no comparably easy way to determine a next OID that’s beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

• The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetxlog`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

The -n (no operation) option instructs `pg_resetxlog` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetxlog` to proceed for real. The -V and --version options print the `pg_resetxlog` version and exit. The options -? and --help show supported arguments, and exit.

1962
Notes

This command must not be used when the server is running. \texttt{pg\_resetxlog} will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow \texttt{pg\_resetxlog} to run. But before you do so, make doubly certain that there is no server process still alive.

\texttt{pg\_resetxlog} works only with servers of the same major version.
**pg_rewind**

**Name**

pg_rewind — synchronize a PostgreSQL data directory with another data directory that was forked from the first one

**Synopsis**

```
pg_rewind [option...] {-D | --target-pgdata} directory {--source-pgdata=directory | --source-server=connstr}
```

**Description**

pg_rewind is a tool for synchronizing a PostgreSQL cluster with another copy of the same cluster, after the clusters’ timelines have diverged. A typical scenario is to bring an old master server back online after failover, as a standby that follows the new master.

The result is equivalent to replacing the target data directory with the source one. All files are copied, including configuration files. The advantage of pg_rewind over taking a new base backup, or tools like rsync, is that pg_rewind does not require reading through all unchanged files in the cluster. That makes it a lot faster when the database is large and only a small portion of it differs between the clusters.

pg_rewind examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster’s `pg_xlog` directory reaching all the way back to the point of divergence. In the typical failover scenario where the target cluster was shut down soon after the divergence, that is not a problem, but if the target cluster had run for a long time after the divergence, the old WAL files might not be present anymore. In that case, they can be manually copied from the WAL archive to the `pg_xlog` directory. Fetching missing files from a WAL archive automatically is currently not supported.

When the target server is started up for the first time after running pg_rewind, it will go into recovery mode and replay all WAL generated in the source server after the point of divergence. If some of the WAL was no longer available in the source server when pg_rewind was run, and therefore could not be copied by pg_rewind session, it needs to be made available when the target server is started up. That can be done by creating a recovery.conf file in the target data directory with a suitable restore_command.

pg_rewind requires that the target server either has the wal_log_hints option enabled in `postgresql.conf` or that data checksums were enabled when the cluster was initialized with initdb. Neither of these are currently on by default. full_page_writes must also be enabled. That is the default.
### Warning

If `pg_rewind` fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

`pg_rewind` will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running `pg_rewind`. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

### Options

`pg_rewind` accepts the following command-line arguments:

- `-D directory`
  - `--target-pgdata=directory`
    - This option specifies the target data directory that is synchronized with the source. The target server must shut down cleanly before running `pg_rewind`.
  - `--source-pgdata=directory`
    - Specifies path to the data directory of the source server, to synchronize the target with. When `-source-pgdata` is used, the source server must be cleanly shut down.
  - `--source-server=connstr`
    - Specifies a libpq connection string to connect to the source PostgreSQL server to synchronize the target with. The connection must be a normal (non-replication) connection with superuser access. The server must be up and running, and must not be in recovery mode.

- `-n`
  - `--dry-run`
    - Do everything except actually modifying the target directory.

- `-P`
  - `--progress`
    - Enables progress reporting. Turning this on will deliver an approximate progress report while copying data over from the source cluster.

- `--debug`
  - Print verbose debugging output that is mostly useful for developers debugging `pg_rewind`.

- `--version`
  - Display version information, then exit.
-?
--help

Show help, then exit.

Environment

When --source-server option is used, pg_rewind also uses the environment variables supported by libpq (see Section 31.14).

Notes

When executing pg_rewind using an online cluster as source which has been recently promoted, it is necessary to execute a CHECKPOINT after promotion so as its control file reflects up-to-date timeline information, which is used by pg_rewind to check if the target cluster can be rewound using the designated source cluster.

How it works

The basic idea is to copy everything from the new cluster to the old cluster, except for the blocks that we know to be the same.

1. Scan the WAL log of the old cluster, starting from the last checkpoint before the point where the new cluster’s timeline history forked off from the old cluster. For each WAL record, make a note of the data blocks that were touched. This yields a list of all the data blocks that were changed in the old cluster, after the new cluster forked off.
2. Copy all those changed blocks from the new cluster to the old cluster.
3. Copy all other files such as clog and configuration files from the new cluster to the old cluster, everything except the relation files.
4. Apply the WAL from the new cluster, starting from the checkpoint created at failover. (Strictly speaking, pg_rewind doesn’t apply the WAL, it just creates a backup label file indicating that when PostgreSQL is started, it will start replay from that checkpoint and apply all the required WAL.)
pg_test_fsync

Name

pg_test_fsync — determine fastest wal_sync_method for PostgreSQL

Synopsis

pg_test_fsync [option...]

Description

pg_test_fsync is intended to give you a reasonable idea of what the fastest wal_sync_method is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by pg_test_fsync might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their transaction logs. pg_test_fsync reports average file sync operation time in microseconds for each wal_sync_method, which can also be used to inform efforts to optimize the value of commit_delay.

Options

pg_test_fsync accepts the following command-line options:

- `f`  
  --filename

  Specifies the file name to write test data in. This file should be in the same file system that the pg_xlog directory is or will be placed in. (pg_xlog contains the WAL files.) The default is pg_test_fsync.out in the current directory.

- `s`  
  --secs-per-test

  Specifies the number of seconds for each test. The more time per test, the greater the test’s accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

- `V`  
  --version

  Print the pg_test_fsync version and exit.

- `?`  
  --help

  Show help about pg_test_fsync command line arguments, and exit.

postgres
pg_test_timing

Name

pg_test_timing — measure timing overhead

Synopsis

pg_test_timing [option...]

Description

pg_test_timing is a tool to measure the timing overhead on your system and confirm that the system time never moves backwards. Systems that are slow to collect timing data can give less accurate EXPLAIN ANALYZE results.

Options

pg_test_timing accepts the following command-line options:

- `d duration`  
  `-d duration`  
  `--duration=duration`  
  Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are more likely to discover problems with the system clock moving backwards. The default test duration is 3 seconds.

- `-V`  
  `--version`  
  Print the pg_test_timing version and exit.

- `?`  
  `--help`  
  Show help about pg_test_timing command line arguments, and exit.

Usage

Interpreting results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860 system
using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 nsec
Histogram of timing durations:
< usec % of total count
1 96.40465 80435604
2 3.59518 2999652
4 0.00015 126
8 0.00002 13
16 0.00000 2

Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (nsec), while the individual timing calls can only resolve down to one microsecond (usec).

Measuring executor timing overhead

When the query executor is running a statement using EXPLAIN ANALYZE, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the psql program:

```
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the EXPLAIN ANALYZE version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what pg_test_timing estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

Changing time sources

On some newer Linux systems, it’s possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower acpi_pm time source, on the same system used for the fast results above:

```
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 nsec
Histogram of timing durations:
< usec % of total count
1  27.84870  1155682
```
In this configuration, the sample EXPLAIN ANALYZE above takes 115.9 ms. That's 1061 nsec of timing overhead, again a small multiple of what's measured directly by this utility. That much timing overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any EXPLAIN ANALYZE totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "18254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you'll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it’s backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
 time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
 time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
Histogram of timing durations:
< usec % of total count
  1  90.23734   27694571
  2  9.75277    2993204
  4  0.00981    3010
  8  0.00007    22
16  0.00000    1
32  0.00000    1
```

1971
Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.

The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It's the preferred way to track the system time when it's supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that’s inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn’t default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it’s known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it’s available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the acpi_pm. The clock derived from acpi_pm will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

EXPLAIN
**pg_upgrade**

**Name**

`pg_upgrade` — upgrade a PostgreSQL server instance

**Synopsis**

```
pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]
```

**Description**

`pg_upgrade` (formerly called `pg_migrator`) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/reload typically required for major version upgrades, e.g. from 8.4.7 to the current major release of PostgreSQL. It is not required for minor version upgrades, e.g. from 9.0.1 to 9.0.4.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. `pg_upgrade` uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, `pg_upgrade` will not be usable for such upgrades. (The community will attempt to avoid such situations.)

`pg_upgrade` does its best to make sure the old and new clusters are binary-compatible, e.g. by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by `pg_upgrade`.

`pg_upgrade` supports upgrades from 8.4.X and later to the current major release of PostgreSQL, including snapshot and alpha releases.

**Options**

`pg_upgrade` accepts the following command-line arguments:

- `-b bindir`
  `---old-bindir=bindir`
  
  the old PostgreSQL executable directory; environment variable PGBINOLD

- `-B bindir`
  `---new-bindir=bindir`
  
  the new PostgreSQL executable directory; environment variable PGBINNEW

- `-c`
  `---check`

  check clusters only, don’t change any data
pg_upgrade

-d datadir
--old-datadir=datadir

the old cluster data directory; environment variable PGDATAOLD

-D datadir
--new-datadir=datadir

the new cluster data directory; environment variable PGDATANEW

-j
--jobs

number of simultaneous processes or threads to use

-k
--link

use hard links instead of copying files to the new cluster

-o options
--old-options options

options to be passed directly to the old postgres command; multiple option invocations are appended

-O options
--new-options options

options to be passed directly to the new postgres command; multiple option invocations are appended

-p port
--old-port=port

the old cluster port number; environment variable PGPORTOLD

-P port
--new-port=port

the new cluster port number; environment variable PGPORTNEW

-r
--retain

retain SQL and log files even after successful completion

-U username
--username=username

cluster's install user name; environment variable PGUSER

-v
--verbose

enable verbose internal logging

-V
--version

display version information, then exit
Usage

These are the steps to perform an upgrade with pg_upgrade:

1. Optionally move the old cluster
   
   If you are using a version-specific installation directory, e.g. `/opt/PostgreSQL/9.1`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.
   
   If your installation directory is not version-specific, e.g. `/usr/local/pgsql`, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

   ```
   mv /usr/local/pgsql /usr/local/pgsql.old
   ```

to rename the directory.

2. For source installs, build the new version
   
   Build the new PostgreSQL source with configure flags that are compatible with the old cluster. pg_upgrade will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

3. Install the new PostgreSQL binaries
   
   Install the new server’s binaries and support files. pg_upgrade is included in a default installation.
   
   For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:

   ```
   make prefix=/usr/local/pgsql.new install
   ```

4. Initialize the new PostgreSQL cluster
   
   Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

5. Install custom shared object files
   
   Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g. `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g. `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

6. Adjust authentication
   
   pg_upgrade will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 31.15).

7. Stop both servers
Make sure both database servers are stopped using, on Unix, e.g.:

- `pg_ctl -D /opt/PostgreSQL/8.4 stop`
- `pg_ctl -D /opt/PostgreSQL/9.0 stop`

or on Windows, using the proper service names:

- `NET STOP postgresql-8.4`
- `NET STOP postgresql-9.0`

Streaming replication and log-shipping standby servers can remain running until a later step.

8. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in section step 10, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary or if the old standby servers are still running.) Also, change `wal_level` to `hot_standby` in the `postgresql.conf` file on the new primary cluster.

9. Run pg_upgrade

Always run the pg_upgrade binary of the new server, not the old one. pg_upgrade requires the specification of the old and new cluster’s data and executable (bin) directories. You can also specify user and port values, and whether you want the data linked instead of copied (the default).

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_xlog` can be on different file systems.) See `pg_upgrade --help` for a full list of options.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```
RUNAS /USER:postgres "CMD.EXE"
SET PATH=%PATH%;C:\Program Files\PostgreSQL\9.0\bin;
```

and then run pg_upgrade with quoted directories, e.g.:

```
pg_upgrade.exe
   --old-datadir "C:\Program Files\PostgreSQL\8.4\data"
   --new-datadir "C:\Program Files\PostgreSQL\9.0\data"
   --old-bindir "C:\Program Files\PostgreSQL\8.4\bin"
   --new-bindir "C:\Program Files\PostgreSQL\9.0\bin"
```

Once started, pg_upgrade will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the `--link` option with `--check` to enable link-mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. pg_upgrade defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the
same time. However, when checking an old running server, the old and new port numbers must be
different.

If an error occurs while restoring the database schema, pg_upgrade will exit and you will have
to revert to the old cluster as outlined in step 16 below. To try pg_upgrade again, you will need
to modify the old cluster so the pg_upgrade schema restore succeeds. If the problem is a contrib
module, you might need to uninstall the contrib module from the old cluster and install it in the
new cluster after the upgrade, assuming the module is not being used to store user data.

10. Upgrade Streaming Replication and Log-Shipping standby servers

If you used link mode and have Streaming Replication (see Section 25.2.5) or Log-Shipping (see
Section 25.2) standby servers, you can follow these steps to quickly upgrade them. You will not be
running pg_upgrade on the standby servers, but rather rsync on the primary. Do not start any servers
yet.

If you did not use link mode, do not have or do not want to use rsync, or want an easier solution, skip
the instructions in this section and simply recreate the standby servers once pg_upgrade completes
and the new primary is running.

a. Install the new PostgreSQL binaries on standby servers

Make sure the new binaries and support files are installed on all standby servers.

b. Make sure the new standby data directories do not exist

Make sure the new standby data directories do not exist or are empty. If initdb was run,
delete the standby servers’ new data directories.

c. Install custom shared object files

Install the same custom shared object files on the new standbys that you installed in the new
primary cluster.

d. Stop standby servers

If the standby servers are still running, stop them now using the above instructions.

e. Save configuration files

Save any configuration files from the old standbys’ data directories you need to keep, e.g.
postgresql.conf, recovery.conf, because these will be overwritten or removed in the
next step.

f. Run rsync

When using link mode, standby servers can be quickly upgraded using rsync. To accomplish
this, from a directory on the primary server that is above the old and new database cluster
directories, run this on the primary for each standby server:

rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster
where old_cluster and new_cluster are relative to the current directory on the primary,
and remote_dir is above the old and new cluster directories on the standby. The directory
structure under the specified directories on the primary and standbys must match. Consult
the rsync manual page for details on specifying the remote directory, e.g.

rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/PostgreSQL/9.5
/opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
You can verify what the command will do using rsync’s --dry-run option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.

What this does is to record the links created by pg_upgrade’s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby’s old cluster and creates links for them in the standby’s new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don’t normally exist on standby servers.

If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:

```
rsync --archive --delete --hard-links --size-only --no-inc-recursive /vol1/pg_tblsp/PG_9.5_201510051 /vol1/pg_tblsp/PG_9.6_201608131 standby.example.com:/vol1/pg_tblsp
```

If you have relocated pg_xlog outside the data directories, rsync must be run on those directories too.

g. Configure streaming replication and log-shipping standby servers

Configure the servers for log shipping. (You do not need to run pg_start_backup() and pg_stop_backup() or take a file system backup as the standbys are still synchronized with the primary.)

11. Restore pg_hba.conf

If you modified pg_hba.conf, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g. postgresql.conf.

12. Start the new server

The new server can now be safely started, and then any rsync’ed standby servers.

13. Post-Upgrade processing

If any post-upgrade processing is required, pg_upgrade will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

```
psql --username postgres --file script.sql postgres
```

The scripts can be run in any order and can be deleted once they have been run.

Caution

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

14. Statistics

Because optimizer statistics are not transferred by pg_upgrade, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.
15. Delete old cluster

Once you are satisfied with the upgrade, you can delete the old cluster’s data directories by running the script mentioned when `pg_upgrade` completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g. `bin`, `share`).

16. Reverting to old cluster

If, after running `pg_upgrade`, you wish to revert to the old cluster, there are several options:

- If the `--check` option was used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was *not* used, the old cluster was unmodified; it can be restarted.
- If the `--link` option was used, the data files might be shared between the old and new cluster:
  - If `pg_upgrade` aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did *not* start the new cluster, the old cluster was unmodified except that, when linking started, a `.old` suffix was appended to `$PGDATA/global/pg_control`. To reuse the old cluster, remove the `.old` suffix from `$PGDATA/global/pg_control`; you can then restart the old cluster.
  - If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

Notes

`pg_upgrade` does not support upgrading of databases containing these `reg*` OID-referencing system data types: `regproc`, `regprocedure`, `regoper`, `regoperator`, `regconfig`, and `regdictionary`. (`regtype` can be upgraded.)

All failure, rebuild, and reindex cases will be reported by `pg_upgrade` if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to `pg_upgrade`, and pass the configuration directory location to the server, e.g. `-d /real-data-directory -o '-D /configuration-directory'`.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set `PGHOST` to point to the old server’s socket location. (This is not relevant on Windows.)

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use `rsync` to create a dirty copy of the old cluster while the server is running, then shut down the
old server and run `rsync --checksum` again to update the copy with any changes to make it consistent. (`--checksum` is necessary because `rsync` only has file modification-time granularity of one second.) You might want to exclude some files, e.g. `postmaster.pid`, as documented in Section 24.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

`initdb`, `pg_ctl`, `pg_dump`, `postgres`
pg_xlogdump

Name

pg_xlogdump — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

Synopsis

pg_xlogdump [option...] [startseg [endseg]]

Description

pg_xlogdump displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

Options

The following command-line options control the location and format of the output:

startseg
   Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

distseg
   Stop after reading the specified log segment file.

-b
   --bkp-details
   Output detailed information about backup blocks.

-e end
   --end=end
   Stop reading at the specified log position, instead of reading to the end of the log stream.

-f
   --follow
   After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

-n limit
   --limit=limit
   Display the specified number of records, then stop.
pg_xlogdump

-p path
--path=path
 Directory in which to find log segment files. The default is to search for them in the pg_xlog subdirectory of the current directory.

-r rmgr
--rmgr=rmgr
 Only display records generated by the specified resource manager. If list is passed as name, print a list of valid resource manager names, and exit.

-s start
--start=start
 Log position at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

-t timeline
--timeline=timeline
 Timeline from which to read log records. The default is to use the value in startseg, if that is specified; otherwise, the default is 1.

-V
--version
 Print the pg_xlogdump version and exit.

-x xid
--xid=xid
 Only display records marked with the given transaction ID.

-z
--stats[=record]
 Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

-?
--help
 Show help about pg_xlogdump command line arguments, and exit.

Notes

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

pg_xlogdump cannot read WAL files with suffix .partial. If those files need to be read, .partial suffix needs to be removed from the file name.

Section 29.5
postgres

Name

postgres — PostgreSQL database server

Synopsis

postgres [option...]

Description

postgres is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running postgres instance. The postgres instance then starts a separate server process to handle the connection.

One postgres instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one postgres instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When postgres starts it needs to know the location of the data area. The location must be specified by the -D option or the PGDATA environment variable; there is no default. Typically, -D or PGDATA points directly to the data area directory created by initdb. Other possible file layouts are discussed in Section 18.2.

By default postgres starts in the foreground and prints log messages to the standard error stream. In practical applications postgres should be started as a background process, perhaps at boot time.

The postgres command can also be called in single-user mode. The primary use for this mode is during bootstrapping by initdb. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

Options

postgres accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 18. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable PGOPTIONS is set, then libpq-based clients will pass that string to the server, which will interpret it as postgres command-line options.
General Purpose

-B  \texttt{nbuffers}

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the shared_buffers configuration parameter.

-c  \texttt{name=value}

Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 18. Most of the other command line options are in fact short forms of such a parameter assignment. \texttt{-c} can appear multiple times to set multiple parameters.

-C  \texttt{name}

Prints the value of the named run-time parameter, and exits. (See the \texttt{-c} option above for details.) This can be used on a running server, and returns values from \texttt{postgresql.conf}, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This option is meant for other programs that interact with a server instance, such as \texttt{pg_ctl}, to query configuration parameter values. User-facing applications should instead use \texttt{SHOW} or the \texttt{pg_settings} view.

-d  \texttt{debug-level}

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass \texttt{-d 0} for a specific session, which will prevent the server log level of the parent \texttt{postgres} process from being propagated to this session.

-D  \texttt{datadir}

Specifies the file system location of the database configuration files. See Section 18.2 for details.

-e

Sets the default date style to “European”, that is \texttt{DMY} ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

-F

Disables \texttt{fsync} calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the \texttt{fsync} configuration parameter. Read the detailed documentation before using this!

-h  \texttt{hostname}

Specifies the IP host name or address on which \texttt{postgres} is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or \texttt{*} to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the \texttt{listen_addresses} configuration parameter.

-i

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting \texttt{listen_addresses} to \texttt{*} in
This option is deprecated since it does not allow access to the full functionality of listen_addresses. It’s usually better to set listen_addresses directly.

\-k directory

Specifies the directory of the Unix-domain socket on which \texttt{postgres} is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally \texttt{/tmp}, but that can be changed at build time. Specifying this option is equivalent to setting the \texttt{unix_socket_directories} configuration parameter.

\-l

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 17.9.

\-N max-connections

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by \texttt{initdb}. Specifying this option is equivalent to setting the max_connections configuration parameter.

\-o extra-options

The command-line-style arguments specified in \texttt{extra-options} are passed to all server processes started by this \texttt{postgres} process.

Spaces within \texttt{extra-options} are considered to separate arguments, unless escaped with a backslash (\); write \texttt{\backslash} to represent a literal backslash. Multiple arguments can also be specified via multiple uses of \texttt{-o}.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the \texttt{postgres} command line.

\-p port

Specifies the TCP/IP port or local Unix domain socket file extension on which \texttt{postgres} is to listen for connections from client applications. Defaults to the value of the \texttt{PGPORT} environment variable, or if \texttt{PGPORT} is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or \texttt{PGPORT}.

\-s

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

\-S work_mem

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the \texttt{work_mem} configuration parameter in Section 18.4.1.

\-V

\--version

Print the \texttt{postgres} version and exit.
--name=value

Sets a named run-time parameter; a shorter form of -c.

--describe-config

This option dumps out the server’s internal configuration variables, descriptions, and defaults in tab-delimited COPY format. It is designed primarily for use by administration tools.

-?

--help

Show help about postgres command line arguments, and exit.

Semi-internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

-f { s | i | o | b | t | n | m | h }

Forbids the use of particular scan and join methods: s and i disable sequential and index scans respectively, o, b and t disable index-only scans, bitmap index scans, and TID scans respectively, while n, m, and h disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the -fs and -fn options simply discourage the optimizer from using those plan types if it has any other alternative.

-n

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that postgres will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.

-O

Allows the structure of system tables to be modified. This is used by initdb.

-P

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

-t pa[rser] | pl[anner] | e[xecutor]

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the -s option.

-T

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have
corrupted some shared state before terminating. This option specifies that `postgres` will stop all other server processes by sending the signal `SIGSTOP`, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.

`-v protocol`

Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

`-W seconds`

A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

**Options for Single-User Mode**

The following options only apply to the single-user mode.

`-s single`

Selects the single-user mode. This must be the first argument on the command line.

`database`

Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

`-E`

Echo all commands.

`-j`

Disables use of newline as a statement delimiter.

`-r filename`

Send all server log output to `filename`. This option is only honored when supplied as a command-line option.

**Environment**

`PGCLIENTENCODING`

Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

`PGDATA`

Default data directory location

`PGDATESTYLE`

Default value of the DateStyle run-time parameter. (The use of this environment variable is deprecated.)
Default port number (preferably set in the configuration file)

Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 17.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of PostgreSQL, and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```bash
$ ps ax | grep postgres
```

or

```bash
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be reserved. For example, many versions of Unix consider port numbers under 1024 to be “trusted” and only permit the Unix superuser to access them.

Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, do not use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in Section 9.26.2 for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal should not be used by users. It is also unwise to send `SIGKILL` to a server process —
the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.

### Bugs

The `--` options will not work on FreeBSD or OpenBSD. Use `-c` instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

### Usage

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with `-D`, or make sure that the environment variable `PGDATA` is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in `psql`. To continue a command across multiple lines, you must type backslash just before each newline except the last one.

But if you use the `-j` command line switch, then newline does not terminate command entry. In this case, the server will read the standard input until the end-of-file (EOF) marker, then process the input as a single command string. Backslash-newline is not treated specially in this case.

To quit the session, type EOF (Control+D, usually). If you’ve used `-j`, two consecutive EOFs are needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-User mode also does not do any background processing, like automatic checkpoints.

### Examples

To start `postgres` in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 <dev/null &
```

To start `postgres` with a specific port, e.g. 1234:

```
$ postgres -p 1234
```

To connect to this server using `psql`, specify this port with the `-p` option:

```
$ psql -p 1234
```

or set the environment variable `PGPORT`: 1990
Named run-time parameters can be set in either of these styles:

$ export PGPORT=1234
$ psql

postgres  -c work_mem=1234
postgres  --work_mem=1234

Either form overrides whatever setting might exist for work_mem in postgresql.conf. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it’s probably better practice to edit the setting in postgresql.conf than to rely on a command-line switch to set a parameter.

VII. Internals

This part contains assorted information that might be of use to PostgreSQL developers.
This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of PostgreSQL, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

48.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.

2. The parser stage checks the query transmitted by the application program for correct syntax and creates a query tree.

3. The rewrite system takes the query tree created by the parser stage and looks for any rules (stored in the system catalogs) to apply to the query tree. It performs the transformations given in the rule bodies.

   One application of the rewrite system is in the realization of views. Whenever a query against a view (i.e., a virtual table) is made, the rewrite system rewrites the user's query to a query that accesses the base tables given in the view definition instead.

4. The planner/optimizer takes the (rewritten) query tree and creates a query plan that will be the input to the executor.

   It does so by first creating all possible paths leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the plan tree and retrieves rows in the way represented by the plan. The executor makes use of the storage system while scanning relations, performs sorts and joins, evaluates qualifications and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL’s internal control and data structures.
48.2. How Connections are Established

PostgreSQL is implemented using a simple “process per user” client/server model. In this model there is one client process connected to exactly one server process. As we do not know ahead of time how many connections will be made, we have to use a master process that spawns a new server process every time a connection is requested. This master process is called postgres and listens at a specified TCP/IP port for incoming connections. Whenever a request for a connection is detected the postgres process spawns a new server process. The server tasks communicate with each other using semaphores and shared memory to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 50. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the backend (server). The query is transmitted using plain text, i.e., there is no parsing done in the frontend (client). The server parses the query, creates an execution plan, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

48.3. The Parser Stage

The parser stage consists of two parts:

- The parser defined in gram.y and scan.l is built using the Unix tools bison and flex.
- The transformation process does modifications and augmentations to the data structures returned by the parser.

48.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a parse tree is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex.

The lexer is defined in the file scan.l and is responsible for recognizing identifiers, the SQL key words etc. For every key word or identifier that is found, a token is generated and handed to the parser.

The parser is defined in the file gram.y and consists of a set of grammar rules and actions that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file scan.l is transformed to the C source file scan.c using the program flex and gram.y is transformed to gram.c using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.
Chapter 48. Overview of PostgreSQL Internals

Note: The mentioned transformations and compilations are normally done automatically using the makefiles shipped with the PostgreSQL source distribution.

A detailed description of bison or the grammar rules given in gram.y would be beyond the scope of this paper. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in gram.y otherwise you won’t understand what happens there.

48.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the transformation process takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the query tree.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (BEGIN, ROLLBACK, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as SELECT or UPDATE), it is okay to start a transaction if we’re not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a FuncCall node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a FuncExpr or Aggref node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

48.4. The PostgreSQL Rule System

PostgreSQL supports a powerful rule system for the specification of views and ambiguous view updates. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using row level processing and was implemented deep in the executor. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.
- The second implementation of the rule system is a technique called query rewriting. The rewrite system is a module that exists between the parser stage and the planner/optimizer. This technique is still implemented.
The query rewriter is discussed in some detail in Chapter 38, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.

48.5. Planner/Optimizer

The task of the planner/optimizer is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

**Note:** In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a Genetic Query Optimizer (see Chapter 57) when the number of joins exceeds a threshold (see geqo_threshold).

The planner’s search procedure actually works with data structures called paths, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged plan tree is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we’ll ignore the distinction between paths and plans.

48.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction `relation.attribute OPR constant`. If `relation.attribute` happens to match the key of the B-tree index and `OPR` is one of the operators listed in the index’s operator class, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query’s `ORDER BY` clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- **nested loop join:** The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)
Chapter 48. Overview of PostgreSQL Internals

- **merge join**: Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.

- **hash join**: the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.

When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than geqo_threshold relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the WHERE qualification (i.e., for which a restriction like where rel1.attr1=rel2.attr2 exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When geqo_threshold is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 57. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do selection (discarding rows that do not meet a specified Boolean condition) and projection (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the WHERE clause and computation of required output expressions to the most appropriate nodes of the plan tree.

### 48.6. Executor

The executor takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a MergeJoin node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to lefttree). The new top node (the top node of the left subplan) is, let’s say, a Sort node and again recursion is needed to obtain an input row. The child node of the Sort might be a SeqScan node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The Sort node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a NULL instead of a row), the Sort code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.
The MergeJoin node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the MergeJoin node returns NULL to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: SELECT, INSERT, UPDATE, and DELETE. For SELECT, the top-level executor code only needs to send each row returned by the query plan tree off to the client. For INSERT, each returned row is inserted into the target table specified for the INSERT. This is done in a special top-level plan node called ModifyTable. (A simple INSERT ... VALUES command creates a trivial plan tree consisting of a single Result node, which computes just one result row, and ModifyTable above it to perform the insertion. But INSERT ... SELECT can demand the full power of the executor mechanism.) For UPDATE, the planner arranges that each computed row includes all the updated column values, plus the TID (tuple ID, or row ID) of the original target row; this data is fed into a ModifyTable node, which uses the information to create a new updated row and mark the old row deleted. For DELETE, the only column that is actually returned by the plan is the TID, and the ModifyTable node simply uses the TID to visit each target row and mark it deleted.
Chapter 49. System Catalogs

The system catalogs are the place where a relational database management system stores schema meta-data, such as information about tables and columns, and internal bookkeeping information. PostgreSQL’s system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are always SQL commands to do that. (For example, CREATE DATABASE inserts a row into the pg_database catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, such as adding index access methods.

49.1. Overview

Table 49-1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

Table 49-1. System Catalogs

</table>
49.2. `pg_aggregate`

The catalog `pg_aggregate` stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate’s name, input and output data types, and other information that is similar to ordinary functions.

</tr>
</tbody>
</table>

New aggregate functions are registered with the CREATE AGGREGATE command. See Section 35.10 for more information about writing aggregate functions and the meaning of the transition functions, etc.

49.3. pg_am

The catalog pg_am stores information about index access methods. There is one row for each index access method supported by the system. The contents of this catalog are discussed in detail in Chapter 58.

### Chapter 49. pg_amop

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a `search` operator or an `ordering` operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed,
though unlikely, for an operator to be used for both search and ordering purposes.)

Table 49-4. pg_amop Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amopfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amoplefttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of operator</td>
</tr>
<tr>
<td>amoprighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of operator</td>
</tr>
<tr>
<td>amopstrategy</td>
<td>int2</td>
<td></td>
<td>Operator strategy number</td>
</tr>
<tr>
<td>amoppurpose</td>
<td>char</td>
<td></td>
<td>Operator purpose, either s for search or o for ordering</td>
</tr>
<tr>
<td>amopopr</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>OID of the operator</td>
</tr>
<tr>
<td>amopmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>amopsortfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator</td>
</tr>
</tbody>
</table>

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying WHERE indexed_column operator constant. Obviously, such an operator must return boolean, and its left-hand input type must match the index’s column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by ORDER BY indexed_column operator constant. Such an operator could return any sortable data type, though again its left-hand input type must match the index’s column data type. The exact semantics of the ORDER BY are specified by the amopsortfamily column, which must reference a B-tree operator family for the operator’s result type.

Note: At present, it’s assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., ASC NULLS LAST. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry’s amopmethod must match the opfmethod of its containing operator family (including amopmethod here is an intentional denormalization of the catalog structure for performance reasons). Also, amoplefttype and amoprighttype must match the oprleft and oprright fields of the referenced pg_operator entry.
49.5. pg_amproc

The catalog pg_amproc stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

Table 49-5. pg_amproc Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amprocfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amproclefttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocrighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocname</td>
<td>int2</td>
<td></td>
<td>Support procedure number</td>
</tr>
<tr>
<td>amproc</td>
<td>regproc</td>
<td>pgProc.oid</td>
<td>OID of the procedure</td>
</tr>
</tbody>
</table>

The usual interpretation of the amproclefttype and amprocrighttype fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There is a notion of “default” support procedures for an index, which are those with amproclefttype and amprocrighttype both equal to the index operator class’s opcintype.

49.6. pg_atrtdfe

The catalog pg_atrtdfe stores column default values. The main information about columns is stored in pg_attribute (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

Table 49-6. pg_atrtdfe Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>adrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>adnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the column</td>
</tr>
</tbody>
</table>
The `adsrc` field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the `adbin` field (with `pg_get_expr` for example) is a better way to display the default value.

### 49.7. `pg_attribute`

The catalog `pg_attribute` stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have `pg_class` entries.)

The term attribute is equivalent to column and is used for historical reasons.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td><code>pg_class.oid</code></td>
<td>The table this column belongs to</td>
</tr>
<tr>

<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attcacheoff</td>
<td>int4</td>
<td></td>
<td>Always -1 in storage, but when loaded into a row descriptor in memory this might be updated to cache the offset of the attribute within the row.</td>
</tr>
<tr>
<td>atttypmod</td>
<td>int4</td>
<td></td>
<td>atttypmod records type-specific data supplied at table creation time (for example, the maximum length of a varchar column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need atttypmod.</td>
</tr>
<tr>
<td>attbyval</td>
<td>bool</td>
<td></td>
<td>A copy of pg_type.typbyval of this column’s type.</td>
</tr>
<tr>
<td>attstorage</td>
<td>char</td>
<td></td>
<td>Normally a copy of pg_type.typstorage of this column’s type. For TOAST-able data types, this can be altered after column creation to control storage policy.</td>
</tr>
<tr>
<td>attalign</td>
<td>char</td>
<td></td>
<td>A copy of pg_type.typalign of this column’s type.</td>
</tr>
<tr>
<td>attnotnull</td>
<td>bool</td>
<td></td>
<td>This represents a not-null constraint.</td>
</tr>
<tr>
<td>atthasdef</td>
<td>bool</td>
<td></td>
<td>This column has a default value, in which case there will be a corresponding entry in the pg_attrdef catalog that actually defines the value.</td>
</tr>
</tbody>
</table>
## Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attisdropped</td>
<td>bool</td>
<td></td>
<td>This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.</td>
</tr>
<tr>
<td>attislocal</td>
<td>bool</td>
<td></td>
<td>This column is defined locally in the relation. Note that a column can be locally defined and inherited simultaneously.</td>
</tr>
<tr>
<td>attinhcount</td>
<td>int4</td>
<td></td>
<td>The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.</td>
</tr>
<tr>
<td>attcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>The defined collation of the column, or zero if the column is not of a collatable data type.</td>
</tr>
<tr>
<td>attacl</td>
<td>aclitem[]</td>
<td></td>
<td>Column-level access privileges, if any have been granted specifically on this column</td>
</tr>
<tr>
<td>attoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level options, as “keyword=value” strings</td>
</tr>
<tr>
<td>attfdwoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level foreign data wrapper options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

In a dropped column’s pg_attribute entry, attypid is reset to zero, but attlen and the other fields copied from pg_type are still valid. This arrangement is needed to cope with the situation where the dropped column’s data type was later dropped, and so there is no pg_type row anymore. attlen and the other fields can be used to interpret the contents of a row of the table.

### 49.8. pg_authid

The catalog pg_authid contains information about database authorization identifiers (roles). A role sub-
Chapter 49. System Catalogs

assumes the concepts of “users” and “groups”. A user is essentially just a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) can have other roles as members; see `pg_auth_members`.

Since this catalog contains passwords, it must not be publicly readable. `pg_roles` is a publicly readable view on `pg_authid` that blanks out the password field.

Chapter 20 contains detailed information about user and privilege management.

Because user identities are cluster-wide, `pg_authid` is shared across all databases of a cluster: there is only one copy of `pg_authid` per cluster, not one per database.

<table>
<thead>
<tr>

</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolpassword</td>
<td>text</td>
<td>Password (possibly encrypted); null if none. If the password is encrypted, this column will begin with the string <code>md5</code> followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user’s password concatenated to their user name. For example, if user <code>joe</code> has password <code>xyzzy</code>, PostgreSQL will store the <code>md5</code> hash of <code>xyzzyjoe</code>. A password that does not follow that format is assumed to be unencrypted.</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestamptz</td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
</tbody>
</table>

#### 49.9. `pg_auth_members`

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

**Table 49-9. `pg_auth_members` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleid</td>
<td>oid</td>
<td>pg_authid.oid</td>

<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of the role that granted this membership</td>
</tr>
<tr>
<td>admin_option</td>
<td>bool</td>
<td></td>
<td>True if <code>member</code> can grant membership in <code>roleid</code> to others</td>
</tr>
</tbody>
</table>

#### 49.10. `pg_cast`

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.
It should be noted that \texttt{pg\_cast} does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in \texttt{pg\_cast}. Another important exception is that “automatic I/O conversion casts”, those performed using a data type’s own I/O functions to convert to or from \texttt{text} or other string types, are not explicitly represented in \texttt{pg\_cast}.

### Table 49-10. \texttt{pg\_cast} Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{oid}</td>
<td>\texttt{oid}</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>\texttt{castsource}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_type.oid}</td>
<td>OID of the source data type</td>
</tr>
<tr>
<td>\texttt{casttarget}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_type.oid}</td>
<td>OID of the target data type</td>
</tr>
<tr>
<td>\texttt{castfunc}</td>
<td>\texttt{oid}</td>
<td>\texttt{pg_proc.oid}</td>
<td>The OID of the function to use to perform this cast. Zero is stored if the cast method doesn’t require a function.</td>
</tr>
<tr>
<td>\texttt{castcontext}</td>
<td>\texttt{char}</td>
<td></td>
<td>Indicates what contexts the cast can be invoked in. \texttt{e} means only as an explicit cast (using \texttt{CAST} or \texttt{::} syntax). \texttt{a} means implicitly in assignment to a target column, as well as explicitly. \texttt{i} means implicitly in expressions, as well as the other cases.</td>
</tr>
<tr>
<td>\texttt{castmethod}</td>
<td>\texttt{char}</td>
<td></td>
<td>Indicates how the cast is performed. \texttt{f} means that the function specified in the \texttt{castfunc} field is used. \texttt{i} means that the input/output functions are used. \texttt{b} means that the types are binary-coercible, thus no conversion is required.</td>
</tr>
</tbody>
</table>

The cast functions listed in \texttt{pg\_cast} must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type \texttt{integer}; it receives the type modifier associated with the
destination type, or -1 if there is none. The third argument, if present, must be type boolean; it receives true if the cast is an explicit cast, false otherwise.

It is legitimate to create a pg_cast entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent “length coercion functions” that coerce values of the type to be legal for a particular type modifier value.

When a pg_cast entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

### 49.11. pg_class

The catalog pg_class catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also pg_index), sequences, views, materialized views, composite types, and TOAST tables; see relkind. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

#### Table 49-11. pg_class Columns

<table>
<thead>
<tr>

<td></td>
<td>Access-method-specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

Several of the Boolean flags in `pg_class` are maintained lazily: they are guaranteed to be true if that’s the correct state, but may not be reset to false immediately when the condition is no longer true. For example, `relhasindex` is set by `CREATE INDEX`, but it is never cleared by `DROP INDEX`. Instead, `VACUUM` clears `relhasindex` if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.
49.12. **pg_collation**

The catalog `pg_collation` describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 22.2 for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

<td>int4</td>
<td></td>
<td>Encoding in which the collation is applicable, or -1 if it works for any encoding</td>
</tr>
<tr>
<td>collcollate</td>
<td>name</td>
<td></td>
<td>LC_COLLATE for this collation object</td>
</tr>
<tr>
<td>collctype</td>
<td>name</td>
<td></td>
<td>LC_CTYPE for this collation object</td>
</tr>
</tbody>
</table>

Note that the unique key on this catalog is `(collname, collencoding, collnamespace)` not just `(collname, collnamespace)`. PostgreSQL generally ignores all collations that do not have `collencoding` equal to either the current database’s encoding or -1, and creation of new entries with the same name as an entry with `collencoding = -1` is forbidden. Therefore it is sufficient to use a qualified SQL name `(schema.name)` to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that `initdb` fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the `template0` database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from `template0`. This would currently have to be done manually.

49.13. **pg_constraint**

The catalog `pg_constraint` stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the `pg_attribute` catalog, not here.
User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

### Table 49-13. `pg_constraint` Columns

<table>
<thead>

</tr>
<tr>
<td>confkey</td>
<td>int2[]</td>
<td>pg_attribute.attnum</td>
<td>If a foreign key, list of the referenced columns</td>
</tr>
<tr>
<td>compfseqop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If a foreign key, list of the equality operators for PK = FK comparisons</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

#### Table 49-1. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conppeqop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If a foreign key, list of the equality operators for PK = PK comparisons</td>
</tr>
<tr>
<td>confseqop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If a foreign key, list of the equality operators for FK = FK comparisons</td>
</tr>
<tr>
<td>conexclop</td>
<td>oid[]</td>
<td>pg_operator.oid</td>
<td>If an exclusion constraint, list of the per-column exclusion operators</td>
</tr>
<tr>
<td>conbin</td>
<td>pg_node_tree</td>
<td></td>
<td>If a check constraint, an internal representation of the expression</td>
</tr>
<tr>
<td>consrc</td>
<td>text</td>
<td></td>
<td>If a check constraint, a human-readable representation of the expression</td>
</tr>
</tbody>
</table>

In the case of an exclusion constraint, `conkey` is only useful for constraint elements that are simple column references. For other cases, a zero appears in `conkey` and the associated index must be consulted to discover the expression that is constrained. (`conkey` thus has the same contents as `pg_index.indkey` for the index.)

**Note:** `consrc` is not updated when referenced objects change; for example, it won’t track renaming of columns. Rather than relying on this field, it’s best to use `pg_get_constraintdef()` to extract the definition of a check constraint.

**Note:** `pg_class.relchecks` needs to agree with the number of check-constraint entries found in this table for each relation.

### 49.14. pg_conversion

The catalog `pg_conversion` describes encoding conversion procedures. See CREATE CONVERSION for more information.

#### Table 49-14. pg_conversion Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>

2025
49.15. **pg_database**

The catalog `pg_database` stores information about the available databases. Databases are created with the CREATE DATABASE command. Consult Chapter 21 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>

<td>bool</td>
<td></td>
<td>If true, then this database can be cloned by any user with CREATEDB privileges; if false, then only superusers or the owner of the database can clone it.</td>
</tr>
<tr>
<td>datallowconn</td>
<td>bool</td>
<td></td>
<td>If false then no one can connect to this database. This is used to protect the template0 database from being altered.</td>
</tr>
<tr>
<td>datconnlimit</td>
<td>int4</td>
<td></td>
<td>Sets maximum number of concurrent connections that can be made to this database. -1 means no limit.</td>
</tr>
<tr>
<td>datlastsysoid</td>
<td>oid</td>
<td></td>
<td>Last system OID in the database; useful particularly to pg_dump</td>
</tr>
<tr>
<td>datfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow pg_clog to be shrunk. It is the minimum of the per-table pg_class.refrozenxid values.</td>
</tr>
</tbody>
</table>
49.16. **pg_db_role_setting**

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relminmxid</code> values.</td>
</tr>
<tr>
<td>dattablespace</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace; in particular, all the non-shared system catalogs will be there.</td>
</tr>
<tr>
<td>datacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

#### Table 49-17. `pg_default_acl` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setdatabase</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the setting is applicable to, or zero if not database-specific</td>

<td>oid</td>
<td>pg_authid.oid</td>
<td>The OID of the role the setting is applicable to, or zero if not role-specific</td>
</tr>
<tr>
<td>setconfig</td>
<td>text[]</td>
<td></td>
<td>Defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

#### 49.17. `pg_default_acl`

The catalog `pg_default_acl` stores initial privileges to be assigned to newly created objects.

A `pg_default_acl` entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = 0`, and “per-schema” entries that reference a particular schema. If a global entry is present then it **overrides** the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be added to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default
privileges for its object, not whatever might be in pg_default_acl at the moment. pg_default_acl is only consulted during object creation.

49.18. pg_depend

The catalog pg_depend records the dependency relationships between database objects. This information allows DROP commands to find which other objects must be dropped by DROP CASCADE or prevent dropping in the DROP RESTRICT case.

See also pg_shdepend, which performs a similar function for dependencies involving objects that are shared across a database cluster.

Table 49-18. pg_depend Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a pg_depend entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by deptype:
Chapter 49. System Catalogs

DEPENDENCY_NORMAL (n)
A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying CASCADE, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.

DEPENDENCY_AUTO (a)
The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of RESTRICT or CASCADE mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

DEPENDENCY_INTERNAL (i)
The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A DROP of the dependent object will be disallowed outright (we’ll tell the user to issue a DROP against the referenced object, instead). A DROP of the referenced object will be propagated through to drop the dependent object whether CASCADE is specified or not. Example: a trigger that’s created to enforce a foreign-key constraint is made internally dependent on the constraint’s pg_constraint entry.

DEPENDENCY_EXTENSION (e)
The dependent object is a member of the extension that is the referenced object (see pg_extension). The dependent object can be dropped only via DROP_EXTENSION on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it’s kept separate for clarity and to simplify pg_dump.

DEPENDENCY_PIN (p)
There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by initdb. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

49.19. pg_description
The catalog pg_description stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the COMMENT command and viewed with psql’s \d commands. Descriptions of many built-in system objects are provided in the initial contents of pg_description.

See also pg_shdescription, which performs a similar function for descriptions involving objects that are shared across a database cluster.

Table 49-19. pg_description Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a comment on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

#### 49.20. \texttt{pg_enum}

The \texttt{pg_enum} catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in \texttt{pg_enum}.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>enumtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The OID of the \texttt{pg_type} entry owning this enum value</td>
</tr>
<tr>
<td>enumsortorder</td>
<td>float4</td>
<td></td>
<td>The sort position of this enum value within its enum type</td>
</tr>
<tr>
<td>enumlabel</td>
<td>name</td>
<td></td>
<td>The textual label for this enum value</td>
</tr>
</tbody>
</table>

The OIDs for \texttt{pg_enum} rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller \texttt{enumsortorder} value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..\texttt{n}. But members added later might be given negative or fractional values of \texttt{enumsortorder}. The only requirement on these
values is that they be correctly ordered and unique within each enum type.

49.21. pg_event_trigger

The catalog pg_event_trigger stores event triggers. See Chapter 37 for more information.

Table 49-21. pg_event_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evtname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique)</td>
</tr>
<tr>
<td>evtevent</td>
<td>name</td>
<td></td>
<td>Identifies the event for which this trigger fires</td>
</tr>
<tr>
<td>evtowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the event trigger</td>
</tr>
<tr>
<td>evtfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>evtenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the event trigger fires. O = trigger fires in “origin” and “local” modes, D = trigger is disabled, R = trigger fires in “replica” mode, A = trigger fires always.</td>
</tr>
<tr>
<td>evttags</td>
<td>text[]</td>
<td></td>
<td>Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.</td>
</tr>
</tbody>
</table>

49.22. pg_extension

The catalog pg_extension stores information about the installed extensions. See Section 35.15 for details about extensions.

Table 49-22. pg_extension Columns

| Name    | Type      | References | Description |
|---------|-----------|------------|-------------|-------------|
|         |           |            |             |             |
### Chapter 49. System Catalogs

#### Name | Type | References | Description
--- | --- | --- | ---
oid | oid | | Row identifier (hidden attribute; must be explicitly selected)

extname | name | | Name of the extension

extowner | oid | pg_authid.oid | Owner of the extension

extnamespace | oid | pg_namespace.oid | Schema containing the extension’s exported objects

extrelocatable | bool | | True if extension can be relocated to another schema

extversion | text | | Version name for the extension

extconfig | oid[] | pg_class.oid | Array of regclass OIDs for the extension’s configuration table(s), or NULL if none

extcondition | text[] | | Array of WHERE-clause filter conditions for the extension’s configuration table(s), or NULL if none

Note that unlike most catalogs with a “namespace” column, extnamespace is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, extnamespace indicates the schema that contains most or all of the extension’s objects. If extrelocatable is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

### 49.23. pg_foreign_data_wrapper

The catalog pg_foreign_data_wrapper stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

#### Table 49-23. pg_foreign_data_wrapper Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>fdwname</td>
<td>name</td>
<td></td>
<td>Name of the foreign-data wrapper</td>
</tr>
<tr>
<td>fdwowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign-data wrapper</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>fdwhandler</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided.</td>
</tr>
<tr>
<td>fdwvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>References a validator function that is responsible for checking the validity of the options given to the foreign-data wrapper, as well as options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided.</td>
</tr>
<tr>
<td>fdwacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
<tr>
<td>fdwoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign-data wrapper specific options, as “keyword=value” strings.</td>
</tr>
</tbody>
</table>

#### 49.24. pg_foreign_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

**Table 49-24. pg_foreign_server Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td></td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>srvowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign server</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

#### Table 49-24. pg_foreign_data_wrapper Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>srvfdw</td>
<td>oid</td>
<td>pg_foreign_data_wrapper</td>
<td>OID of the foreign-data wrapper of this foreign server</td>
</tr>
<tr>

<td>text</td>
<td></td>
<td>Type of the server (optional)</td>
</tr>
<tr>
<td>srvversion</td>
<td>text</td>
<td></td>
<td>Version of the server (optional)</td>
</tr>
<tr>
<td>srvacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>srvoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign server specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

#### 49.25. pg_foreign_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

Table 49-25. pg_foreign_table Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the <code>pg_class</code> entry for this foreign table</td>
</tr>
<tr>
<td>ftserver</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>OID of the foreign server for this foreign table</td>
</tr>
<tr>
<td>ftoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign table options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

#### 49.26. pg_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

Table 49-26. pg_index Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>bool</td>
<td></td>
<td>If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)</td>
</tr>
<tr>
<td>indisreplident</td>
<td>bool</td>
<td></td>
<td>If true this index has been chosen as “replica identity” using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</td>
</tr>
<tr>
<td>indkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
</tbody>
</table>
### 49.27. pg_inherits

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indcollation</td>
<td>oidvector</td>
<td>pg_collation.oid</td>
<td>For each column in the index key, this contains the OID of the collation to use for the index.</td>
</tr>
<tr>
<td>indclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>For each column in the index key, this contains the OID of the operator class to use. See <code>pg_opclass</code> for details.</td>
</tr>
<tr>
<td>indoption</td>
<td>int2vector</td>
<td></td>
<td>This is an array of <code>indnatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index’s access method.</td>
</tr>
<tr>
<td>indexprs</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code>. Null if all index attributes are simple references.</td>
</tr>
<tr>
<td>indpred</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for partial index predicate. Null if not a partial index.</td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td>lanplcallfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.</td>
</tr>
<tr>
<td>laninline</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.</td>
</tr>
<tr>
<td>lanvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.</td>
</tr>
<tr>
<td>lanacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
</tbody>
</table>

#### 49.29. `pg_largeobject`

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be 2041.
Chapter 49. System Catalogs

LOBLKSIZE (which is currently BLCKSZ/4, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, pg_largeobject was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use pg_largeobject_metadata to obtain a list of large object OIDs.

Table 49-29. pg_largeobject Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>
<td>oid</td>
<td>pg_largeobject_metadata.oid</td>
<td>Identifier of the large object that includes this page</td>
</tr>
<tr>
<td>pageno</td>
<td>int4</td>
<td></td>
<td>Page number of this page within its large object (counting from zero)</td>
</tr>
<tr>
<td>data</td>
<td>bytea</td>
<td></td>
<td>Actual data stored in the large object. This will never be more than LOBLKSIZE bytes and might be less.</td>
</tr>
</tbody>
</table>

Each row of pg_largeobject holds data for one page of a large object, beginning at byte offset (pageno * LOBLKSIZE) within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than LOBLKSIZE bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

49.30. pg_largeobject_metadata

The catalog pg_largeobject_metadata holds metadata associated with large objects. The actual large object data is stored in pg_largeobject.

Table 49-30. pg_largeobject_metadata Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lomowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the large object</td>
</tr>
<tr>
<td>lomacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>
### 49.31. pg_namespace

The catalog `pg_namespace` stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>nspname</td>
<td>name</td>
<td></td>
<td>Name of the namespace</td>
</tr>
<tr>
<td>nspowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the namespace</td>
</tr>
<tr>
<td>nspacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

### 49.32. pg_opclass

The catalog `pg_opclass` defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column’s data type as their left-hand input.

Operator classes are described at length in Section 35.14.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opcmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator class is for</td>
</tr>
<tr>
<td>opcname</td>
<td>name</td>
<td></td>
<td>Name of this operator class</td>
</tr>
<tr>
<td>opcnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator class</td>
</tr>
<tr>
<td>opcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator class</td>
</tr>
</tbody>
</table>
An operator class’s `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

### 49.33. `pg_operator`

The catalog `pg_operator` stores information about operators. See CREATE OPERATOR and Section 35.12 for more information.

**Table 49-33. `pg_operator` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>oprname</td>
<td>name</td>
<td></td>
<td>Name of the operator</td>
</tr>
<tr>
<td>oprnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this operator</td>
</tr>
<tr>
<td>oprowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator</td>
</tr>
<tr>
<td>oprkind</td>
<td>char</td>
<td></td>
<td><code>b</code> = infix (“both”), <code>l</code> = prefix (“left”), <code>r</code> = postfix (“right”)</td>
</tr>
<tr>
<td>oprcanmerge</td>
<td>bool</td>
<td></td>
<td>This operator supports merge joins</td>
</tr>
<tr>
<td>oprcanhash</td>
<td>bool</td>
<td></td>
<td>This operator supports hash joins</td>
</tr>
<tr>
<td>oprleft</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the left operand</td>
</tr>
<tr>
<td>oprright</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the right operand</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oprresult</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the result</td>
</tr>
<tr>
<td>oprcom</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Commutator of this operator, if any</td>
</tr>
<tr>
<td>oprnegate</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Negator of this operator, if any</td>
</tr>
<tr>
<td>oprcode</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Function that implements this operator</td>
</tr>
<tr>
<td>oprrest</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Restriction selectivity estimation function for this operator</td>
</tr>
<tr>
<td>oprjoin</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Join selectivity estimation function for this operator</td>
</tr>
</tbody>
</table>

Unused column contain zeroes. For example, oprleft is zero for a prefix operator.

49.34. pg_opfamily

The catalog pg_opfamily defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all “compatible”, in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 35.14.

Table 49-34. pg_opfamily Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opfmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>opfname</td>
<td>name</td>
<td></td>
<td>Name of this operator family</td>
</tr>
<tr>
<td>opfnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>

The majority of the information defining an operator family is not in its pg_opfamily row, but in the associated rows in pg_amop, pg_amproc, and pg_opclass.
49.35. **pg_pltemplate**

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>
<td>Name of the language this template is for</td>
</tr>
<tr>
<td>tmpltrusted</td>
<td>boolean</td>
<td>True if language is considered trusted</td>
</tr>
<tr>
<td>tmpldbcreate</td>
<td>boolean</td>
<td>True if language may be created by a database owner</td>
</tr>
<tr>
<td>tmplhandler</td>
<td>text</td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplinline</td>
<td>text</td>
<td>Name of anonymous-block handler function, or null if none</td>
</tr>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td>Name of validator function, or null if none</td>
</tr>
<tr>
<td>tmpllibrary</td>
<td>text</td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td>Access privileges for template (not actually used)</td>
</tr>
</tbody>
</table>

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

**Note:** It is likely that `pg_pltemplate` will be removed in some future release of PostgreSQL, in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

49.36. **pg_policy**

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be added as a security-barrier qualification to queries that include the table, and the expression to be added as a `WITH CHECK` option for queries that attempt to add new records to the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>
<td>Name of the language this template is for</td>
</tr>
<tr>
<td>tmpltrusted</td>
<td>boolean</td>
<td>True if language is considered trusted</td>
</tr>
<tr>
<td>tmpldbcreate</td>
<td>boolean</td>
<td>True if language may be created by a database owner</td>
</tr>
<tr>
<td>tmplhandler</td>
<td>text</td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplinline</td>
<td>text</td>
<td>Name of anonymous-block handler function, or null if none</td>
</tr>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td>Name of validator function, or null if none</td>
</tr>
<tr>
<td>tmpllibrary</td>
<td>text</td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td>Access privileges for template (not actually used)</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

### Table 49-37. `pg_policy` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>polname</td>
<td>name</td>
<td></td>
<td>The name of the policy</td>
</tr>
<tr>
<td>polrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table to which the policy applies</td>
</tr>
<tr>
<td>polcmd</td>
<td>char</td>
<td></td>
<td>The command type to which the policy is applied: r for SELECT, a for INSERT, w for UPDATE, d for DELETE, or * for all</td>
</tr>
<tr>
<td>polroles</td>
<td>oid[]</td>
<td>pg_authid.oid</td>
<td>The roles to which the policy is applied</td>
</tr>
<tr>
<td>polqual</td>
<td>pg_node_tree</td>
<td></td>
<td>The expression tree to be added to the security barrier qualifications for queries that use the table</td>
</tr>
<tr>
<td>polwithcheck</td>
<td>pg_node_tree</td>
<td></td>
<td>The expression tree to be added to the WITH CHECK qualifications for queries that attempt to add rows to the table</td>
</tr>
</tbody>
</table>

**Note:** Policies stored in `pg_policy` are applied only when `pg_class.relrowsecurity` is set for their table.

---

### 49.37. `pg_proc`

The catalog `pg_proc` stores information about functions (or procedures). See CREATE FUNCTION and Section 35.3 for more information.

The table contains data for aggregate functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

#### Table 49-37. `pg_proc` Columns

<table>
<thead>
<tr>
<th>Name</th>

</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proargtypes</td>
<td>oidvector</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes only input arguments (including INOUT and VARIADIC arguments), and thus represents the call signature of the function.</td>
</tr>
<tr>
<td>proallargtypes</td>
<td>oid[]</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons proargtypes is subscripted from 0.</td>
</tr>
<tr>
<td>proargmodes</td>
<td>char[]</td>
<td></td>
<td>An array with the modes of the function arguments, encoded as i for IN arguments, o for OUT arguments, b for INOUT arguments, v for VARIADIC arguments, t for TABLE arguments. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>proargnames</td>
<td>text[]</td>
<td></td>
<td>An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>proargdefaults</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for default values. This is a list with proargdefaults elements, corresponding to the last $N$ input arguments (i.e., the last $N$ proargtypes positions). If none of the arguments have defaults, this field will be null.</td>
</tr>
<tr>
<td>protrftypes</td>
<td>oid[]</td>
<td></td>
<td>Data type OIDs for which to apply transforms.</td>
</tr>
<tr>
<td>prosrc</td>
<td>text</td>
<td></td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin</td>
<td>text</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proconfig</td>
<td>text[]</td>
<td></td>
<td>Function’s local settings for run-time configuration variables</td>
</tr>
<tr>
<td>proacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, prosrc contains the function’s C-language name (link symbol). For all other currently-known language types, prosrc contains the function’s source text. probin is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

49.38. pg_range

The catalog pg_range stores information about range types. This is in addition to the types’ entries in pg_type.

Table 49-38. pg_range Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypeid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngcollation</td>
<td>oid</td>
<td>pg_collation.oid</td>
<td>OID of the collation used for range comparisons, or 0 if none</td>
</tr>
<tr>
<td>rngsubopc</td>
<td>oid</td>
<td>pg_opclass.oid</td>
<td>OID of the subtype’s operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to convert a range value into canonical form, or 0 if none</td>
</tr>
<tr>
<td>rngsubdiff</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the function to return the difference between two element values as double precision, or 0 if none</td>
</tr>
</tbody>
</table>

rngsubopc (plus rngcollation, if the element type is collatable) determines the sort ordering used by the range type. rngcanonical is used when the element type is discrete. rngsubdiff is optional but
Chapter 49. System Catalogs

should be supplied to improve performance of GiST indexes on the range type.

49.39. *pg_replication_origin*

The *pg_replication_origin* catalog contains all replication origins created. For more on replication origins see Chapter 47.

Table 49-39. *pg_replication_origin* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roident</td>
<td>Oid</td>
<td>A unique, cluster-wide identifier for the replication origin. Should never leave the system.</td>
</tr>
<tr>
<td>roname</td>
<td>text</td>
<td>The external, user defined, name of a replication origin.</td>
</tr>
</tbody>
</table>

49.40. *pg_rewrite*

The catalog *pg_rewrite* stores rewrite rules for tables and views.

Table 49-40. *pg_rewrite* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>Expression tree (in the form of a nodeToString() representation) for the rule’s qualifying condition</td>
</tr>
<tr>
<td>ev_action</td>
<td>pg_node_tree</td>
<td></td>
<td>Query tree (in the form of a nodeToString() representation) for the rule’s action</td>
</tr>
</tbody>
</table>

**Note:** `pg_class.relhasrules` must be true if a table has any rules in this catalog.

### 49.41. pg_seclabel

The catalog `pg_seclabel` stores security labels on database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 49.72.

See also `pg_shseclabel`, which performs a similar function for security labels of database objects that are shared across a database cluster.

#### Table 49-41. pg_seclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
</tbody>
</table>
49.42. pg_shdepend

The catalog pg_shdepend records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also pg_depend, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, pg_shdepend is shared across all databases of a cluster: there is only one copy of pg_shdepend per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the dependent object is in, or zero for a shared object</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog)</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
</tbody>
</table>
In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

**SHARED_DEPENDENCY_POLICY (r)**

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

**SHARED_DEPENDENCY_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.

### 49.43. `pg_shdescription`

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the COMMENT command and viewed with psql’s `\d` commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

**Table 49-43. `pg_shdescription` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

### 49.44. `pg_shseclabel`

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 49.72.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

#### Table 49-44. `pg_shseclabel` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

### 49.45. `pg_statistic`

The catalog `pg_statistic` stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with `stainherit = false`, for each table column that has been analyzed. If the table has inheritance children, a second entry with `stainherit = true` is also created. This row represents the column’s statistics over the inheritance tree, i.e., statistics for the data you’d see with `SELECT`
column FROM table*, whereas the stainherit = false row represents the results of SELECT column FROM ONLY table.

pg_statistic also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, starelid references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have stainherit = false.

Since different kinds of statistics might be appropriate for different kinds of data, pg_statistic is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in pg_statistic. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see src/include/catalog/pg_statistic.h.

pg_statistic should not be readable by the public, since even statistical information about a table’s contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) pg_stats is a publicly readable view on pg_statistic that only exposes information about those tables that are readable by the current user.

Table 49-45. pg_statistic Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table or index that the described column belongs to</td>
</tr>
<tr>
<td>staattnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the described column</td>
</tr>
<tr>
<td>stainherit</td>
<td>bool</td>
<td></td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td></td>
<td>The fraction of the column’s entries that are null</td>
</tr>
<tr>
<td>stawidth</td>
<td>int4</td>
<td></td>
<td>The average stored width, in bytes, of nonnull entries</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------</td>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td></td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by stadistinct = -0.4. A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>
<td></td>
<td>A code number indicating the kind of statistics stored in the Nth “slot” of the pg_statistic row.</td>
</tr>
<tr>
<td>staopN</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>An operator used to derive the statistics stored in the Nth “slot”. For example, a histogram slot would show the &lt; operator that defines the sort order of the data.</td>
</tr>
<tr>
<td>stanumbersN</td>
<td>float4[]</td>
<td></td>
<td>Numerical statistics of the appropriate kind for the Nth “slot”, or null if the slot kind does not involve numerical values</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stavaluesN</td>
<td>anyarray</td>
<td></td>
<td>Column data values of the appropriate kind for the Nth “slot”, or null if</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>the slot kind does not store any data values. Each array’s element</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>values are actually of the specific column’s data type, or a related</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>type such as an array’s element type, so there is no way to define these</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>columns’ type more specifically than anyarray.</td>
</tr>
</tbody>
</table>

49.46. pg_tablespace

The catalog pg_tablespace stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, pg_tablespace is shared across all databases of a cluster: there is only one copy of pg_tablespace per cluster, not one per database.

Table 49-46. pg_tablespace Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>spcname</td>
<td>name</td>
<td></td>
<td>Tablespace name</td>
</tr>
<tr>
<td>spcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the tablespace, usually the user who created it</td>
</tr>
<tr>
<td>spcacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>spcoptions</td>
<td>text[]</td>
<td></td>
<td>Tablespace-level options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>
49.47. *pg_transform*

The catalog *pg_transform* stores information about transforms, which are a mechanism to adapt data types to procedural languages. See CREATE TRANSFORM for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trftype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the data type this transform is for</td>
</tr>
<tr>
<td>trflang</td>
<td>oid</td>
<td>pg_language.oid</td>
<td>OID of the language this transform is for</td>
</tr>
<tr>
<td>trffromsql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.</td>
</tr>
<tr>
<td>trftosql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if this operation is not supported.</td>
</tr>
</tbody>
</table>

49.48. *pg_trigger*

The catalog *pg_trigger* stores triggers on tables and views. See CREATE TRIGGER for more information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>tgrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tgname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>tgtype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>tgenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the trigger fires.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>O = trigger fires in “origin” and “local” modes, D = trigger is disabled,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>R = trigger fires in “replica” mode, A = trigger fires always.</td>
</tr>
<tr>
<td>tgisinternal</td>
<td>bool</td>
<td></td>
<td>True if trigger is internally generated (usually, to enforce the constraint</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>identified by tgconstraint)</td>
</tr>
<tr>
<td>tgconstrrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table referenced by a referential integrity constraint</td>
</tr>
<tr>
<td>tgconstrindid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The index supporting a unique, primary key, referential integrity, or</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>exclusion constraint</td>
</tr>
<tr>
<td>tgconstraint</td>
<td>oid</td>
<td>pg_constraint.oid</td>
<td>The pg_constraint entry associated with the trigger, if any</td>
</tr>
<tr>
<td>tgdeferrable</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tginitdeferred</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs</td>
<td>int2</td>
<td></td>
<td>Number of argument strings passed to trigger function</td>
</tr>
<tr>
<td>tgattr</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>Column numbers, if trigger is column-specific; otherwise an empty array</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated</td>
</tr>
<tr>
<td>tgqual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodeToString() representation) for the trigger’s WHEN condition, or null if none</td>
</tr>
</tbody>
</table>

Currently, column-specific triggering is supported only for UPDATE events, and so tgattr is relevant only for that event type. tgtype might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in tgattr.

**Note:** When tgconstraint is nonzero, tgconstrrelid, tgconstrindid, tgdeferrable, and tgnitdeferred are largely redundant with the referenced pg_constraint entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note:** pg_class.relhastriggers must be true if a relation has any triggers in this catalog.

### 49.49. pg_ts_config

The pg_ts_config catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the pg_ts_config entry, but the token-to-dictionary mapping is defined by subsidiary entries in pg_ts_config_map.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 49-49. pg_ts_config Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>cfgname</td>
<td>name</td>
<td></td>
<td>Text search configuration name</td>
</tr>
<tr>
<td>cfgnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this configuration</td>
</tr>
</tbody>
</table>
### 49.50. `pg_ts_config_map`

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 49-50. `pg_ts_config_map` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid</td>
<td><code>pg_ts_config.oid</code></td>
<td>The OID of the <code>pg_ts_config</code> entry owning this map entry</td>
</tr>
<tr>
<td>maptokentype</td>
<td>integer</td>
<td></td>
<td>A token type emitted by the configuration’s parser</td>
</tr>
<tr>
<td>mapseqno</td>
<td>integer</td>
<td></td>
<td>Order in which to consult this entry (lower <code>mapseqnos</code> first)</td>
</tr>
<tr>
<td>mapdict</td>
<td>oid</td>
<td><code>pg_ts_dict.oid</code></td>
<td>The OID of the text search dictionary to consult</td>
</tr>
</tbody>
</table>

### 49.51. `pg_ts_dict`

The `pg_ts_dict` catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string `dictinitoption`, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 49-51. `pg_ts_dict` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>
Chapter 49. System Catalogs

<table>

<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this dictionary</td>
</tr>
<tr>
<td>dictowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the dictionary</td>
</tr>
<tr>
<td>dicttemplate</td>
<td>oid</td>
<td>pg_ts_template.oid</td>
<td>The OID of the text search template for this dictionary</td>
</tr>
<tr>
<td>dictinitoption</td>
<td>text</td>
<td></td>
<td>Initialization option string for the template</td>
</tr>
</tbody>
</table>

49.52. *pg_ts_parser*

The *pg_ts_parser* catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 49-52. *pg_ts_parser* Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>

<td>name</td>
<td></td>
<td>Text search parser name</td>
</tr>
<tr>
<td>prsnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this parser</td>
</tr>
<tr>
<td>prsstart</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s startup function</td>
</tr>
<tr>
<td>prstoken</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s next-token function</td>
</tr>
<tr>
<td>prsend</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s shutdown function</td>
</tr>
<tr>
<td>prsheadline</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s headline function</td>
</tr>
</tbody>
</table>
### 49.53. `pg_ts_template`

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

#### Table 49-53. `pg_ts_template` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code></td>
<td><code>oid</code></td>

<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td><code>tmplname</code></td>
<td><code>name</code></td>
<td></td>
<td>Text search template name</td>
</tr>
<tr>
<td><code>tmplnamespace</code></td>
<td><code>oid</code></td>
<td><code>pg_namespace.oid</code></td>
<td>The OID of the namespace that contains this template</td>
</tr>
<tr>
<td><code>tmplinit</code></td>
<td><code>regproc</code></td>
<td><code>pg_proc.oid</code></td>
<td>OID of the template’s initialization function</td>
</tr>
<tr>
<td><code>tmpllexize</code></td>
<td><code>regproc</code></td>
<td><code>pg_proc.oid</code></td>
<td>OID of the template’s lexize function</td>
</tr>
</tbody>
</table>

### 49.54. `pg_type`

The catalog `pg_type` stores information about data types. Base types and enum types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

#### Table 49-54. `pg_type` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oid</code></td>
<td><code>oid</code></td>

<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>typnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this type</td>
</tr>
<tr>
<td>typowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the type</td>
</tr>
<tr>
<td>typlen</td>
<td>int2</td>
<td></td>
<td>For a fixed-size type, typlen is the number of bytes in the internal representation of the type. But for a variable-length type, typlen is negative. -1 indicates a “varlena” type (one that has a length word). -2 indicates a null-terminated C string.</td>
</tr>
<tr>
<td>typbyval</td>
<td>bool</td>
<td></td>
<td>typbyval determines whether internal routines pass a value of this type by value or by reference. typbyval had better be false if typlen is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that typbyval can be false even if the length would allow pass-by-value.</td>
</tr>
<tr>
<td>typctype</td>
<td>char</td>
<td></td>
<td>typctype is b for a base type, c for a composite type (e.g., a table’s row type), d for a domain, e for an enum type, p for a pseudo-type, or r for a range type. See also typrelid and typbasetype.</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typcategory</td>
<td>char</td>
<td></td>
<td>typcategory is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 49-55.</td>
</tr>
<tr>
<td>typispreferred</td>
<td>bool</td>
<td></td>
<td>True if the type is a preferred cast target within its typcategory</td>
</tr>
<tr>
<td>typisdefined</td>
<td>bool</td>
<td></td>
<td>True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When typisdefined is false, nothing except the type name, namespace, and OID can be relied on.</td>
</tr>
<tr>
<td>typdelim</td>
<td>char</td>
<td></td>
<td>Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.</td>
</tr>
<tr>
<td>typrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>If this is a composite type (see typtype), then this column points to the pg_class entry that defines the corresponding table. (For a free-standing composite type, the pg_class entry doesn’t really represent a table, but it is needed anyway for the type’s pg_attribute entries to link to.) Zero for non-composite types.</td>

| typalign | char |            | typalign is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:  
  • c = char alignment, i.e., no alignment needed.  
  • s = short alignment (2 bytes on most machines).  
  • i = int alignment (4 bytes on most machines).  
  • d = double alignment (8 bytes on many machines, but by no means all).  

**Note**: For types used in system tables, it is critical that the size and alignment defined in \texttt{pg_type} agree with the way that the compiler will lay out the column in a structure representing a table row. 2071

| typstorage      | char |            | typstorage tells for varlena types (those with `typlen = -1`) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:  
|                 |      |            | • p: Value must always be stored plain.  
|                 |      |            | • e: Value can be stored in a “secondary” relation (if relation has one, see `pg_class.reltoastrelid`).  
|                 |      |            | • m: Value can be stored compressed inline.  
|                 |      |            | • x: Value can be stored compressed inline or stored in “secondary” storage.  
<p>|                 |      |            | Note that m columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first). |
| typnotnull      | bool |            | typnotnull represents a not-null constraint on a type. Used for domains only. |
| typbasetype     | oid  | pg_type.oid| If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain. |</p>

49.56. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 34) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it’s usually better to use the information schema if it provides all the information you need.

Table 49-57 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 27-2.

Except where noted, all the views described here are read-only.

Table 49-57. System Views
### 49.57. `pg_available_extensions`

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

#### Table 49-58. `pg_available_extensions` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>

<td>requires</td>
<td>name[]</td>
<td>Names of prerequisite extensions, or NULL if none</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extension_versions` view is read only.

### 49.59. `pg_cursors`  

The `pg_cursors` view lists the cursors that are currently available. Cursors can be defined in several ways:

- via the DECLARE statement in SQL
• via the Bind message in the frontend/backend protocol, as described in Section 50.2.3
• via the Server Programming Interface (SPI), as described in Section 44.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared WITH HOLD. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

### Table 49-60. `pg_cursors` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>

<tr>
<td>is_holdable</td>
<td>boolean</td>
<td><code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise</td>
</tr>
<tr>
<td>is_binary</td>
<td>boolean</td>
<td><code>true</code> if the cursor was declared BINARY; <code>false</code> otherwise</td>
</tr>
<tr>
<td>is_scrollable</td>
<td>boolean</td>
<td><code>true</code> if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise</td>
</tr>
<tr>
<td>creation_time</td>
<td>timestamptz</td>
<td>The time at which the cursor was declared</td>
</tr>
</tbody>
</table>

The `pg_cursors` view is read only.

### 49.60. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server’s configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the current contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)
Chapter 49. System Catalogs

The `pg_file_settings` view can be read only by superusers.

Table 49-61. `pg_file_settings` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Full path name of the configuration file</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file where the entry appears</td>
</tr>
<tr>
<td>seqno</td>
<td>integer</td>
<td>Order in which the entries are processed (1..n)</td>
</tr>
<tr>
<td>name</td>
<td>text</td>
<td>Configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Value to be assigned to the parameter</td>
</tr>
<tr>
<td>applied</td>
<td>boolean</td>
<td>True if the value can be applied successfully</td>
</tr>
<tr>
<td>error</td>
<td>text</td>
<td>If not null, an error message indicating why this entry could not be applied</td>
</tr>
</tbody>
</table>

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied` = false is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See Section 18.1 for more information about the various ways to change run-time parameters.

49.61. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

Table 49-62. `pg_group` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>

</tr>
<tr>
<td>indexdef</td>
<td>text</td>
<td></td>
<td>Index definition (a reconstructed CREATE INDEX command)</td>
</tr>
</tbody>
</table>

### 49.63. pg_locks

The view `pg_locks` provides access to information about the locks held by open transactions within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object might appear many times, if multiple transactions are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

#### Table 49-64. pg_locks Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype</td>

</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>OID of the lock target within its system catalog, or null if the target is not a general database object</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objsubid</td>
<td>smallint</td>
<td></td>
<td>Column number targeted by the lock (the classid and objid refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object.</td>
</tr>
<tr>
<td>virtualtransaction</td>
<td>text</td>
<td></td>
<td>Virtual ID of the transaction that is holding or awaiting this lock.</td>
</tr>
<tr>
<td>pid</td>
<td>integer</td>
<td></td>
<td>Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction.</td>
</tr>
<tr>
<td>mode</td>
<td>text</td>
<td></td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3).</td>
</tr>
<tr>
<td>granted</td>
<td>boolean</td>
<td></td>
<td>True if lock is held, false if lock is awaited.</td>
</tr>
<tr>
<td>fastpath</td>
<td>boolean</td>
<td></td>
<td>True if lock was taken via fast path, false if taken via main lock table.</td>
</tr>
</tbody>
</table>

`granted` is true in a row representing a lock held by the indicated transaction. False indicates that this transaction is currently waiting to acquire this lock, which implies that some other transaction is holding a conflicting lock mode on the same lockable object. The waiting transaction will sleep until the other lock is released (or a deadlock situation is detected). A single transaction can be waiting to acquire at most one lock at a time.

Every transaction holds an exclusive lock on its virtual transaction ID for its entire duration. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on its permanent transaction ID until it ends. When one transaction finds it necessary to wait specifically for another transaction, it does so by attempting to acquire share lock on the other transaction ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a transaction is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.
Advisory locks can be acquired on keys consisting of either a single bigint value or two integer values. A bigint key is displayed with its high-order half in the classid column, its low-order half in the objid column, and objsubid equal to 1. The original bigint value can be reassembled with the expression (classid::bigint << 32) | objid::bigint. Integer keys are displayed with the first key in the classid column, the second key in the objid column, and objsubid equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the database column is meaningful for an advisory lock.

pg_locks provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its relation column can be joined against pg_class.oid to identify locked relations, this will only work correctly for relations in the current database (those for which the database column is either the current database’s OID or zero).

The pid column can be joined to the pid column of the pg_stat_activity view to get more information on the session holding or waiting to hold each lock, for example

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
  ON pl.pid = psa.pid;
```

Also, if you are using prepared transactions, the virtualtransaction column can be joined to the transaction column of the pg_prepared_xacts view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

```sql
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
  ON pl.virtualtransaction = '-1/' || ppx.transaction;
```

The pg_locks view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and fast-path locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with fastpath = true) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.
49.64. pg_matviews

The view pg_matviews provides access to useful information about each materialized view in the database.

Table 49-65. pg_matviews Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>

</tr>
<tr>
<td>with_check</td>
<td>text</td>
<td>The expression added to the WITH CHECK qualifications for queries that attempt to add rows to this table</td>
</tr>
</tbody>
</table>

#### 49.66. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See `PREPARE` for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the `DEALLOCATE` command).

**Table 49-67. pg_prepared_statements Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The identifier of the prepared statement</td>

<tr>
<td>prepared</td>
<td>timestamp with time zone</td>
<td></td>
<td>Time at which the transaction was prepared for commit</td>
</tr>
<tr>
<td>owner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of the user that executed the transaction</td>
</tr>
<tr>
<td>database</td>
<td>name</td>
<td>pg_database.datname</td>
<td>Name of the database in which the transaction was executed</td>
</tr>
</tbody>
</table>

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a
consistent set of results, while not blocking normal operations longer than necessary. Nonetheless there
could be some impact on database performance if this view is frequently accessed.

49.68. **pg_replication_origin_status**

The `pg_replication_origin_status` view contains information about how far replay for a certain
origin has progressed. For more on replication origins see Chapter 47.

<table>
<thead>
<tr>
<th>Table 49-69. <code>pg_replication_origin_status</code> Columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>local_id</td>
</tr>
<tr>
<td>external_id</td>
</tr>
<tr>
<td>remote_lsn</td>
</tr>
<tr>
<td>local_lsn</td>
</tr>
</tbody>
</table>

49.69. **pg_replication_slots**

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the
database cluster, along with their current state.

For more on replication slots, see Section 25.2.6 and Chapter 46.

<table>
<thead>
<tr>
<th>Table 49-70. <code>pg_replication_slots</code> Columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>slot_name</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>

</tbody>
</table>
## Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>restart_lsn</td>
<td>pg_lsn</td>
<td></td>
<td>The address (LSN) of oldest WAL which still might be required by the consumer of this slot and thus won’t be automatically removed during checkpoints.</td>
</tr>
</tbody>
</table>

### 49.70. pg_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

**Table 49-71. pg_roles Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolname</td>
<td>name</td>
<td></td>
<td>Role name</td>
</tr>
<tr>
<td>rolsuper</td>
<td>bool</td>
<td></td>
<td>Role has superuser privileges</td>
</tr>
<tr>
<td>rolinherit</td>
<td>bool</td>
<td></td>
<td>Role automatically inherits privileges of roles it is a member of</td>
</tr>
<tr>
<td>rolcreaterole</td>
<td>bool</td>
<td></td>
<td>Role can create more roles</td>
</tr>
<tr>

<td>bool</td>
<td></td>
<td>Role can create databases</td>
</tr>
<tr>
<td>rolcanlogin</td>
<td>bool</td>
<td></td>
<td>Role can log in. That is, this role can be given as the initial session authorization identifier</td>
</tr>
<tr>
<td>rolreplication</td>
<td>bool</td>
<td></td>
<td>Role is a replication role. That is, this role can initiate streaming replication (see Section 25.2.5) and set/unset the system backup mode using <code>pg_start_backup</code> and <code>pg_stop_backup</code></td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>rolconnlimit</td>
<td>int4</td>
<td></td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
<tr>
<td>rolpassword</td>
<td>text</td>
<td></td>
<td>Not the password (always reads as *********)</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestamp</td>
<td></td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
<tr>
<td>rolbypassrls</td>
<td>bool</td>
<td></td>
<td>Role bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>rolconfig</td>
<td>text[]</td>
<td></td>
<td>Role-specific defaults for run-time configuration variables</td>
</tr>
<tr>
<td>oid</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of role</td>
</tr>
</tbody>
</table>

### 49.71. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

#### Table 49-72. pg_rules Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td>pg_rewrite.rulename</td>
<td>Name of rule</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The `pg_rules` view excludes the ON SELECT rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.  

2090
49.72. **pg_seclabels**

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td><code>pg_class</code>.<code>oid</code></td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>objtype</td>
<td>text</td>
<td></td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace</td>
<td>oid</td>
<td><code>pg_namespace</code>.<code>oid</code></td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
<tr>
<td>objname</td>
<td>text</td>
<td></td>
<td>The name of the object to which this label applies, as text.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td><code>pg_seclabel</code>.<code>provider</code></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td><code>pg_seclabel</code>.<code>label</code></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

49.73. **pg_settings**

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the `SHOW` and `SET` commands. It also provides access to some facts about each parameter that are not directly available from `SHOW`, such as minimum and maximum values.
### Table 49-74. pg_settings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Run-time configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Current value of the parameter</td>
</tr>
<tr>
<td>unit</td>
<td>text</td>
<td>Implicit unit of the parameter</td>

<tr>
<td>category</td>
<td>text</td>
<td>Logical group of the parameter</td>
</tr>
<tr>
<td>short_desc</td>
<td>text</td>
<td>A brief description of the parameter</td>
</tr>
<tr>
<td>extra_desc</td>
<td>text</td>
<td>Additional, more detailed, description of the parameter</td>
</tr>
<tr>
<td>context</td>
<td>text</td>
<td>Context required to set the parameter’s value (see below)</td>
</tr>
<tr>
<td>vartype</td>
<td>text</td>
<td>Parameter type (bool, enum, integer, real, or string)</td>
</tr>
<tr>
<td>source</td>
<td>text</td>
<td>Source of the current parameter value</td>
</tr>
<tr>
<td>min_val</td>
<td>text</td>
<td>Minimum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>max_val</td>
<td>text</td>
<td>Maximum allowed value of the parameter (null for non-numeric values)</td>
</tr>
<tr>
<td>enumvals</td>
<td>text[]</td>
<td>Allowed values of an enum parameter (null for non-enum values)</td>
</tr>
<tr>
<td>boot_val</td>
<td>text</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>text</td>
<td>Value that RESET would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using include directives in configuration files</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)</td>
</tr>
<tr>
<td>pending_restart</td>
<td>boolean</td>
<td>true if the value has been changed in the configuration file but needs a restart; or false otherwise.</td>
</tr>
</tbody>
</table>

There are several possible values of context. In order of decreasing difficulty of changing the setting, they are:

**internal**

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.

**postmaster**

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower context types can also be set at server start time.

**sighup**

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

**superuser-backend**

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

**backend**

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq's `PGOPTIONS` environment variable); any user can make such a change for his session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.
superuser

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change his session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 18.1 for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

### 49.74. `pg_shadow`

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`.

The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

#### Table 49-75. `pg_shadow` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>User name</td>

<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td></td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td></td>
<td>User is a superuser</td>
</tr>
<tr>
<td>userepl</td>
<td>bool</td>
<td></td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>usebypassrls</td>
<td>bool</td>
<td></td>
<td>User bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
</tbody>
</table>
49.75. **pg_stats**

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table</td>
</tr>
<tr>
<td>attname</td>
<td>name</td>
<td>pg_attribute.attname</td>
<td>Name of the column described by this row</td>
</tr>
<tr>
<td>inherited</td>
<td>bool</td>
<td></td>
<td>If true, this row includes inheritance child columns, not just the values in the specified table</td>
</tr>
<tr>
<td>null_frac</td>
<td>real</td>
<td></td>
<td>Fraction of column entries that are null</td>
</tr>
<tr>
<td>avg_width</td>
<td>integer</td>
<td></td>
<td>Average width in bytes of column’s entries</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>n_distinct</td>
<td>real</td>
<td></td>
<td>If greater than zero, the estimated number of distinct values in the column. If less than zero, the negative of the number of distinct values divided by the number of rows. (The negated form is used when <code>ANALYZE</code> believes that the number of distinct values is likely to increase as the table grows; the positive form is used when the column seems to have a fixed number of possible values.) For example, -1 indicates a unique column in which the number of distinct values is the same as the number of rows.</td>
</tr>
<tr>
<td>most_common_vals</td>
<td>anyarray</td>
<td></td>
<td>A list of the most common values in the column. (Null if no values seem to be more common than any others.)</td>
</tr>
<tr>
<td>most_common_freqs</td>
<td>real[]}</td>
<td></td>
<td>A list of the frequencies of the most common values, i.e., number of occurrences of each divided by total number of rows. (Null when <code>most_common_vals</code> is.)</td>
</tr>
</tbody>
</table>
### Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>histogram_bounds</td>
<td>anyarray</td>
<td></td>
<td>A list of values that divide the column’s values into groups of approximately equal population. The values in most_common_vals, if present, are omitted from this histogram calculation. (This column is null if the column data type does not have a <code>&lt;</code> operator or if the most_common_vals list accounts for the entire population.)</td>
</tr>
<tr>
<td>correlation</td>
<td>real</td>
<td></td>
<td>Statistical correlation between physical row ordering and logical ordering of the column values. This ranges from -1 to +1. When the value is near -1 or +1, an index scan on the column will be estimated to be cheaper than when it is near zero, due to reduction of random access to the disk. (This column is null if the column data type does not have a <code>&lt;</code> operator.)</td>
</tr>
<tr>
<td>most_common_elems</td>
<td>anyarray</td>
<td></td>
<td>A list of non-null element values most often appearing within values of the column. (Null for scalar types.)</td>
</tr>
</tbody>
</table>
Chapter 49. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>most_common_elem_freqs</td>
<td>real[]</td>
<td></td>
<td>A list of the frequencies of the most common element values, i.e., the fraction of rows containing at least one instance of the given value. Two or three additional values follow the per-element frequencies; these are the minimum and maximum of the preceding per-element frequencies, and optionally the frequency of null elements. (Null when most_common elems is.)</td>
</tr>
<tr>
<td>elem_count_histogram</td>
<td>real[]</td>
<td></td>
<td>A histogram of the counts of distinct non-null element values within the values of the column, followed by the average number of distinct non-null elements. (Null for scalar types.)</td>
</tr>
</tbody>
</table>

The maximum number of entries in the array fields can be controlled on a column-by-column basis using the `ALTER TABLE SET STATISTICS` command, or globally by setting the default_statistics_target runtime parameter.

### 49.76. pg_tables

The view `pg_tables` provides access to useful information about each table in the database.

**Table 49-77. pg_tables Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table</td>
</tr>
<tr>
<td>tableowner</td>
<td>name</td>
<td>pg_authid rolname</td>
<td>Name of table’s owner</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------</td>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td>pg_tablespace.spcname</td>
<td>Name of tablespace containing table (null if default for database)</td>
</tr>
<tr>
<td>hasindexes</td>
<td>boolean</td>
<td>pg_class.relhasindex</td>
<td>True if table has (or recently had) any indexes</td>
</tr>
<tr>
<td>hasrules</td>
<td>boolean</td>
<td>pg_class.relhasrules</td>
<td>True if table has (or once had) rules</td>
</tr>
<tr>
<td>hastriggers</td>
<td>boolean</td>
<td>pg_class.relhastrig</td>
<td>True if table has (or once had) triggers</td>
</tr>
<tr>
<td>rowsecurity</td>
<td>boolean</td>
<td>pg_class.relrowsec</td>
<td>True if row security is enabled on the table</td>
</tr>
</tbody>
</table>

### 49.77. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the timezone_abbreviations runtime parameter is modified.

#### Table 49-78. pg_timezone_abbrevs Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if this is a daylight-savings abbreviation</td>
</tr>
</tbody>
</table>

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.4 for more information). In such cases this view presents their current meaning.

### 49.78. pg_timezone_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL uses UT1 rather than UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`. 
Chapter 49. System Catalogs

Table 49-79. pg_timezone_names Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if currently observing daylight savings</td>
</tr>
</tbody>
</table>

49.79. pg_user

The view pg_user provides access to information about database users. This is simply a publicly readable view of pg_shadow that blanks out the password field.

Table 49-80. pg_user Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td>User is a superuser</td>
</tr>
<tr>
<td>userepl</td>
<td>bool</td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>usebypassrls</td>
<td>bool</td>
<td>User bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>abstime</td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

49.80. pg_user_mappings

The view pg_user_mappings provides access to information about user mappings. This is essentially a publicly readable view of pg_user_mapping that leaves out the options field if the user has no rights to use it.
Chapter 49. System Catalogs

Table 49-81. pg_user_mappings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td>pg_user_mapping.oid</td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td>pg_foreign_server.srvname</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public</td>
</tr>
<tr>
<td>username</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the umoptions column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds USAGE privilege on it
- current user is the server owner and mapping is for PUBLIC
- current user is a superuser

49.81. pg_views

The view pg_views provides access to useful information about each view in the database.

Table 49-82. pg_views Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing view</td>
</tr>
<tr>
<td>viewname</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of view</td>
</tr>
<tr>
<td>viewowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of view’s owner</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>View definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>
Chapter 50. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g. the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

50.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as NOTIFY) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as COPY.
Chapter 50. Frontend/Backend Protocol

50.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message into a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

50.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don’t handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal’s query. In the case of a query that returns rows (SELECT, SHOW, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

50.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.
The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

50.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 50.5.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, COPY, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

50.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as pg_hba.conf) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI and SSPI, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

ErrorResponse

The connection attempt has been rejected. The server then immediately closes the connection.

AuthenticationOk

The authentication exchange is successfully completed.

AuthenticationKerberosV5

The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.
Chapter 50. Frontend/Backend Protocol

AuthenticationCleartextPassword

The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.

AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a PasswordMessage with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e. beginning with `_pq_`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.
Chapter 50. Frontend/Backend Protocol

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

BackendKeyData
This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

ParameterStatus
This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 50.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

ReadyForQuery
Start-up is completed. The frontend can now issue commands.

ErrorResponse
Start-up failed. The connection is closed after sending this message.

NoticeResponse
A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

50.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but
the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**
An SQL command completed normally.

**CopyInResponse**
The backend is ready to copy data from the frontend to a table; see Section 50.2.5.

**CopyOutResponse**
The backend is ready to copy data from a table to the frontend; see Section 50.2.5.

**RowDescription**
Indicates that rows are about to be returned in response to a `SELECT`, `FETCH`, etc query. The contents of this message describe the column layout of the rows. This will be followed by a `DataRow` message for each row being returned to the frontend.

**DataRow**
One of the set of rows returned by a `SELECT`, `FETCH`, etc query.

**EmptyQueryResponse**
An empty query string was recognized.

**ErrorResponse**
An error has occurred.

**ReadyForQuery**
Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

**NoticeResponse**
A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a `SELECT` query (or other queries that return row sets, such as `EXPLAIN` or `SHOW`) normally consists of `RowDescription`, zero or more `DataRow` messages, and then `CommandComplete`. `COPY` to or from the frontend invokes special protocol as described in Section 50.2.5. All other query types normally produce only a `CommandComplete` message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is `EmptyQueryResponse` followed by `ReadyForQuery`. 

Chapter 50. Frontend/Backend Protocol
In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a `FETCH` from a cursor declared with the `BINARY` option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 50.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.

### 50.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

**Note:** A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols ($n$) used in the query string. Another special case is that a parameter’s type can be specified as `void` (that is, the OID of the `void` pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function’s parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if $3$ and $4$ are specified as having type `void`.

**Note:** The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined.
by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using \texttt{PREPARE} and \texttt{EXECUTE}.

Once a prepared statement exists, it can be readied for execution using a \texttt{Bind} message. The \texttt{Bind} message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any \texttt{void} parameters in the Parse message, pass \texttt{NULL} values for them in the \texttt{Bind} message.) \texttt{Bind} also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either \texttt{BindComplete} or \texttt{ErrorResponse}.

\textbf{Note}: The choice between text and binary output is determined by the format codes given in \texttt{Bind}, regardless of the SQL command involved. The \texttt{BINARY} attribute in cursor declarations is irrelevant when using extended query protocol.

Query planning typically occurs when the \texttt{Bind} message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent \texttt{Bind} messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next \texttt{Bind} statement specifying the unnamed portal as destination is issued. (Note that a simple \texttt{Query} message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another \texttt{Bind} message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using \texttt{DECLARE CURSOR} and \texttt{FETCH}.

Once a portal exists, it can be executed using an \texttt{Execute} message. The \texttt{Execute} message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to \texttt{Execute} are the same as those described above for queries issued via simple query protocol, except that \texttt{Execute} doesn’t cause \texttt{ReadyForQuery} or \texttt{RowDescription} to be issued.

If \texttt{Execute} terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a \texttt{PortalSuspended} message; the appearance of this message tells the frontend that another \texttt{Execute} should be issued against the same portal to complete the operation. The \texttt{CommandComplete} message indicating completion of the source SQL command is not sent until the portal’s execution is completed. Therefore, an \texttt{Execute} phase is always terminated by the appearance of exactly one of these messages: \texttt{CommandComplete}, \texttt{EmptyQueryResponse} (if the portal was created from an empty query string), \texttt{ErrorResponse}, or \texttt{PortalSuspended}.

At completion of each series of extended-query messages, the frontend should issue a \texttt{Sync} message. This parameterless message causes the backend to close the current transaction if it’s not inside a \texttt{BEGIN/COMMIT} transaction block (“close” meaning to commit if no error, or roll back if error). Then a \texttt{ReadyForQuery} response is issued. The purpose of \texttt{Sync} is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues \texttt{ErrorResponse}, then reads and discards messages until a \texttt{Sync} is reached, then issues \texttt{ReadyForQuery}. 

2109
and returns to normal message processing. (But note that no skipping occurs if an error is detected while processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

**Note:** Sync does not cause a transaction block opened with `BEGIN` to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

**Tip:** In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note:** The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or NoData messages.
50.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database’s pg_proc system catalog. The client must have execute permission for the function.

**Note:** The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

- ErrorResponse
  - An error has occurred.
- FunctionCallResponse
  - The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)
- ReadyForQuery
  - Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.
- NoticeResponse
  - A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

50.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).
In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the COPY command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the COPY command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a COPY FROM STDIN.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a COPY TO STDOUT SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the COPY started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 50.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.

There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a START_REPLICATION statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone message, the connection goes into copy-in mode, and the server may not send any more CopyData messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend reverts to the command-processing mode. In the event of a backend-detected error during copy-both mode, the backend will issue an ErrorResponse message, discard frontend messages until a Sync message is received, and then issue ReadyForQuery and return to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy in both directions; no CopyDone should be sent in this case. See Section 50.3 for more information on the subprotocol transmitted over copy-both mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given COPY operation will use the same format, but the message design does not assume this.)
50.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend’s command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a SET SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are server_version, server_encoding, client_encoding, application_name, is_superuser, session_authorization, DateStyle, IntervalStyle, TimeZone, integer_datetimes, and standard_conforming_strings. (server_encoding, TimeZone, and integer_datetimes were not reported by releases before 8.0; standard_conforming_strings was not reported by releases before 8.1; IntervalStyle was not reported by releases before 8.4; application_name was not reported by releases before 9.0.) Note that server_version, server_encoding and integer_datetimes are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same channel name.

**Note:** At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

50.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency; we don’t want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection.
The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 50.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.

Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by recontacting the server if it doesn’t want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-`SELECT` query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (`BEGIN ... COMMIT` sequence) then its results might be committed before the disconnection is recognized.

### 50.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 17.9.
To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing \texttt{S} or \texttt{N}, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after \texttt{S}, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after \texttt{N}, send the usual StartupMessage and proceed without encryption.

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

\section*{50.3. Streaming Replication Protocol}

To initiate streaming replication, the frontend sends the \texttt{replication} parameter in the startup message. A Boolean value of \texttt{true} tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Replication commands are logged in the server log when \texttt{log\_replication\_commands} is enabled. Passing \texttt{database} as the value instructs walsender to connect to the database specified in the \texttt{dbname} parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other \texttt{libpq}-using tool with a connection string including the \texttt{replication} option, e.g.:

\begin{verbatim}
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"
\end{verbatim}

However it is often more useful to use \texttt{pg\_receivexlog} (for physical replication) or \texttt{pg\_recvlogical} (for logical replication).

The commands accepted in walsender mode are:

\textbf{IDENTIFY\_SYSTEM}

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

\begin{verbatim}
<table>
<thead>
<tr>
<th>systemid</th>
<th>timeline</th>
</tr>
</thead>
</table>
\end{verbatim}

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

\begin{verbatim}
<table>
<thead>
<tr>
<th>timeline</th>
</tr>
</thead>
</table>
\end{verbatim}

Current TimelineID. Also useful to check that the standby is consistent with the master.
xlogpos
Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

dbname
Database connected to or NULL.

TIMELINE_HISTORY tli
Requests the server to send over the timeline history file for timeline tli. Server replies with a result set of a single row, containing two fields:

filename
Filename of the timeline history file, e.g. 00000002.history.

content
Contents of the timeline history file.

CREATE_REPLICATION_SLOT slot_name { PHYSICAL | LOGICAL output_plugin }
Create a physical or logical replication slot. See Section 25.2.6 for more about replication slots.

slot_name
The name of the slot to create. Must be a valid replication slot name (see Section 25.2.6.1).

output_plugin
The name of the output plugin used for logical decoding (see Section 46.6).

START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]
Instructs server to start streaming WAL, starting at WAL position XXX/XXX. If TIMELINE option is specified, streaming starts on timeline tli; otherwise, the server’s current timeline is selected. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

If a slot’s name is provided via slot_name, it will be updated as replication progresses so that the server knows which WAL segments, and if hot_standby_feedback is on which transactions, are still needed by the standby.

If the client requests a timeline that’s not the latest, but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested startpoint, up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with CommandComplete without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server’s history. The first column is the next timeline’s ID, and the second column is the XLOG position where the switch happened. Usually, the switch position is the end of the WAL that was streamed, but there
are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends CommandComplete message, and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1('w')
Identifies the message as WAL data.

Int64
The starting point of the WAL data in this message.

Int64
The current end of WAL on the server.

Int64
The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte:n
A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.

Primary keepalive message (B)

Byte1('k')
Identifies the message as a sender keepalive.

Int64
The current end of WAL on the server.

Int64
The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.
The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

- **Byte1('r')**
  - Identifies the message as a receiver status update.
- **Int64**
  - The location of the last WAL byte + 1 received and written to disk in the standby.
- **Int64**
  - The location of the last WAL byte + 1 flushed to disk in the standby.
- **Int64**
  - The location of the last WAL byte + 1 applied in the standby.
- **Int64**
  - The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
- **Byte1**
  - If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

- **Byte1('h')**
  - Identifies the message as a Hot Standby feedback message.
- **Int64**
  - The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.
- **Int32**
  - The standby’s current xmin. This may be 0, if the standby is sending notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.
- **Int32**
  - The standby’s current epoch.
START_REPLICATION SLOT \texttt{slot\_name} LOGICAL \texttt{XXX/XXX} [(\texttt{option\_name} \texttt{option\_value}) [...]]

Instructs server to start streaming WAL for logical replication, starting at WAL position \texttt{XXX/XXX}. The server can reply with an error, e.g. if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

The messages inside the CopyBothResponse messages are of the same format documented for \texttt{START\_REPLICATION} \ldots PHYSICAL.

The output plugin associated with the selected slot is used to process the output for streaming.

\textbf{SLOT \texttt{slot\_name}}

The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with \texttt{CREATE\_REPLICATION\_SLOT} in LOGICAL mode.

\texttt{XXX/XXX}

The WAL position to begin streaming at.

\textbf{option\_name}

The name of an option passed to the slot’s logical decoding plugin.

\textbf{option\_value}

Optional value, in the form of a string constant, associated with the specified option.

\texttt{DROP\_REPLICATION\_SLOT} \texttt{slot\_name}

Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use by an active connection, this command fails.

\texttt{slot\_name}

The name of the slot to drop.

\texttt{BASE\_BACKUP [LABEL \texttt{‘label’}] [PROGRESS] [FAST] [WAL] [NOWAIT] [MAX\_RATE \texttt{rate}] [TABLESPACE\_MAP]}

Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The following options are accepted:

\textbf{LABEL \texttt{‘label’}}

Sets the label of the backup. If none is specified, a backup label of base backup will be used. The quoting rules for the label are the same as a standard SQL string with standard_conforming_strings turned on.

\textbf{PROGRESS}

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and may as such have a negative impact on the performance - in particular it may take longer before the first data is streamed. Since the database files can change during the backup, the size...
Chapter 50. Frontend/Backend Protocol

is only approximate and may both grow and shrink between the time of approximation and the sending of the actual files.

**FAST**
- Request a fast checkpoint.

**WAL**
- Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the pg_xlog directory of the base directory tar file.

**NOWAIT**
- By default, the backup will wait until the last required xlog segment has been archived, or emit a warning if log archiving is not enabled. Specifying `NOWAIT` disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

**MAX_RATE rate**
- Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

**TABLESPACE_MAP**
- Include information about symbolic links present in the directory pg_tblspc in a file named `tablespace_map`. The tablespace map file includes each symbolic link name as it exists in the directory `pg_tblspc/` and the full path of that symbolic link.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

- **spcoid**
  - The oid of the tablespace, or NULL if it’s the base directory.

- **spclocation**
  - The full path of the tablespace directory, or NULL if it’s the base directory.

- **size**
  - The approximate size of the tablespace, if progress report has been requested; otherwise it’s NULL.

After the second regular result set, one or more CopyResponse results will be sent, one for PGDATA and one for each additional tablespace other than pg_default and pg_global. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of
zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

• postmaster.pid
• postmaster.opts
• various temporary files created during the operation of the PostgreSQL server
• pg_xlog, including subdirectories. If the backup is run with WAL files included, a synthesized version of pg_xlog will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
• pg_replslot is copied as an empty directory.
• Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in pg_tblspc are maintained.)

Owner, group and file mode are set if the underlying file system on the server supports it.

Once all tablespaces have been sent, a final regular result set will be sent. This result set contains the end position of the backup, given in XLogRecPtr format as a single column in a single row.

50.4. Message Data Types

This section describes the base data types used in messages.

\textbf{Int}_n(i)

An \textit{n}-bit integer in network byte order (most significant byte first). If \textit{i} is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

\textbf{Int}_n[k]

An array of \textit{k} \textit{n}-bit integers, each in network byte order. The array length \textit{k} is always determined by an earlier field in the message. Eg. Int16[M].

\textbf{String}(s)

A null-terminated string (C-style string). There is no specific length limitation on strings. If \textit{s} is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

\textbf{Note: There is no predefined limit} on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that's not feasible, read the full string and discard trailing characters that don’t fit into your fixed-size buffer.

\textbf{Byte}_n(c)

Exactly \textit{n} bytes. If the field width \textit{n} is not a constant, it is always determinable from an earlier field in the message. If \textit{c} is specified it is the exact value. Eg. Byte2, Byte1('n').

2121
50.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(0)
Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(2)
Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(3)
Specifies that a clear-text password is required.
AuthenticationMD5Password (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(12)
Length of message contents in bytes, including self.

Int32(5)
Specifies that an MD5-encrypted password is required.

Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(6)
Specifies that an SCM credentials message is required.

AuthenticationGSS (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.

Int32(7)
Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)

Byte1('R')
Identifies the message as an authentication request.

Int32(8)
Length of message contents in bytes, including self.
Chapter 50. Frontend/Backend Protocol

Int32(9)
   Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1('R')
   Identifies the message as an authentication request.
Int32
   Length of message contents in bytes, including self.
Int32(8)
   Specifies that this message contains GSSAPI or SSPI data.
Byte
   GSSAPI or SSPI authentication data.

BackendKeyData (B)

Byte1('K')
   Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.
Int32(12)
   Length of message contents in bytes, including self.
Int32
   The process ID of this backend.
Int32
   The secret key of this backend.

Bind (F)

Byte1('B')
   Identifies the message as a Bind command.
Int32
   Length of message contents in bytes, including self.
String
   The name of the destination portal (an empty string selects the unnamed portal).
String
   The name of the source prepared statement (an empty string selects the unnamed prepared statement).
Chapter 50. Frontend/Backend Protocol

Int16

The number of parameter format codes that follow (denoted \( C \) below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

Int16[\( C \)]

The parameter format codes. Each must presently be zero (text) or one (binary).

Int16

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

Int32

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

Byte\( n \)

The value of the parameter, in the format indicated by the associated format code. \( n \) is the above length.

After the last parameter, the following fields appear:

Int16

The number of result-column format codes that follow (denoted \( R \) below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

Int16[\( R \)]

The result-column format codes. Each must presently be zero (text) or one (binary).

BindComplete (B)

Byte1('2')

Identifies the message as a Bind-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CancelRequest (F)

Int32(16)

Length of message contents in bytes, including self.
Chapter 50. Frontend/Backend Protocol

Int32(80877102)
The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32
The process ID of the target backend.

Int32
The secret key for the target backend.

Close (F)

Byte1('C')
Identifies the message as a Close command.

Int32
Length of message contents in bytes, including self.

Byte1
'S' to close a prepared statement; or 'P' to close a portal.

String
The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')
Identifies the message as a Close-complete indicator.

Int32(4)
Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')
Identifies the message as a command-completed response.

Int32
Length of message contents in bytes, including self.

String
The command tag. This is usually a single word that identifies which SQL command was completed.
For an **INSERT** command, the tag is **INSERT oid rows**, where `rows` is the number of rows inserted. `oid` is the object ID of the inserted row if `rows` is 1 and the target table has OIDs; otherwise `oid` is 0.

For a **DELETE** command, the tag is **DELETE rows** where `rows` is the number of rows deleted.

For an **UPDATE** command, the tag is **UPDATE rows** where `rows` is the number of rows updated.

For a **SELECT** or **CREATE TABLE AS** command, the tag is **SELECT rows** where `rows` is the number of rows retrieved.

For a **MOVE** command, the tag is **MOVE rows** where `rows` is the number of rows the cursor's position has been changed by.

For a **FETCH** command, the tag is **FETCH rows** where `rows` is the number of rows that have been retrieved from the cursor.

For a **COPY** command, the tag is **COPY rows** where `rows` is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

**CopyData (F & B)**

Byte1(‘d’)

Identifies the message as **COPY** data.

Int32

Length of message contents in bytes, including self.

* Byte

Data that forms part of a **COPY** data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

**CopyDone (F & B)**

Byte1(‘c’)

Identifies the message as a **COPY**-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

**CopyFail (F)**

Byte1(‘f’)

Identifies the message as a **COPY**-failure indicator.

Int32

Length of message contents in bytes, including self.
String

An error message to report as the cause of failure.

CopyInResponse (B)

Byte1('G')

Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1('H')

Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted \( N \) below).

Int16[\( N \)]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.
CopyBothResponse (B)

Byte1('W')

Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32

Length of message contents in bytes, including self.

Int8

0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16

The number of columns in the data to be copied (denoted $N$ below).

Int16[$N$]

The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1('D')

Identifies the message as a data row.

Int32

Length of message contents in bytes, including self.

Int16

The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32

The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte$n$

The value of the column, in the format indicated by the associated format code. $n$ is the above length.

Describe (F)

Byte1('D')

Identifies the message as a Describe command.
Chapter 50. Frontend/Backend Protocol

Int32
Length of message contents in bytes, including self.

Byte1
'S' to describe a prepared statement; or 'P' to describe a portal.

String
The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).

EmptyQueryResponse (B)

Byte1('I')
Identifies the message as a response to an empty query string. (This substitutes for Command-Complete.)

Int32(4)
Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1('E')
Identifies the message as an error.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 50.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

Execute (F)

Byte1('E')
Identifies the message as an Execute command.

Int32
Length of message contents in bytes, including self.
String
The name of the portal to execute (an empty string selects the unnamed portal).

Int32
Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)

Byte1(‘H’)
Identifies the message as a Flush command.

Int32(4)
Length of message contents in bytes, including self.

FunctionCall (F)

Byte1(‘F’)
Identifies the message as a function call.

Int32
Length of message contents in bytes, including self.

Int32
Specifies the object ID of the function to call.

Int16
The number of argument format codes that follow (denoted C below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[C]
The argument format codes. Each must presently be zero (text) or one (binary).

Int16
Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32
The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte\text{n}
The value of the argument, in the format indicated by the associated format code. \text{n} is the above length.
After the last argument, the following field appears:

Int16

The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)
Byte1('V')
Identifies the message as a function call result.

Int32
Length of message contents in bytes, including self.

Int32
The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte n
The value of the function result, in the format indicated by the associated format code. n is the above length.

NegotiateProtocolVersion (B)
Byte1('v')
Identifies the message as a protocol version negotiation message.

Int32
Length of message contents in bytes, including self.

Int32
Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32
Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String
The option name.

NoData (B)

Byte1('n')
Identifies the message as a no-data indicator.
Chapter 50. Frontend/Backend Protocol

Int32(4)
Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')
Identifies the message as a notice.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 50.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

NotificationResponse (B)

Byte1('A')
Identifies the message as a notification response.

Int32
Length of message contents in bytes, including self.

Int32
The process ID of the notifying backend process.

String
The name of the channel that the notify has been raised on.

String
The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')
Identifies the message as a parameter description.

Int32
Length of message contents in bytes, including self.
Chapter 50. Frontend/Backend Protocol

Int16
   The number of parameters used by the statement (can be zero).
Then, for each parameter, there is the following:

Int32
   Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')
   Identifies the message as a run-time parameter status report.
Int32
   Length of message contents in bytes, including self.
String
   The name of the run-time parameter being reported.
String
   The current value of the parameter.

Parse (F)

Byte1('P')
   Identifies the message as a Parse command.
Int32
   Length of message contents in bytes, including self.
String
   The name of the destination prepared statement (an empty string selects the unnamed prepared statement).
String
   The query string to be parsed.
Int16
   The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.
Then, for each parameter, there is the following:
Int32

Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1('1')

Identifies the message as a Parse-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1('p')

Identifies the message as a password response. Note that this is also used for GSSAPI and SSPI response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).

Int32

Length of message contents in bytes, including self.

String

The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')

Identifies the message as a portal-suspended indicator. Note this only appears if an Execute message’s row-count limit was reached.

Int32(4)

Length of message contents in bytes, including self.

Query (F)

Byte1('Q')

Identifies the message as a simple query.

Int32

Length of message contents in bytes, including self.
String
The query string itself.

ReadyForQuery (B)

Byte1('Z')
Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a new query cycle.

Int32(5)
Length of message contents in bytes, including self.

Byte1
Current backend transaction status indicator. Possible values are 'I' if idle (not in a transaction block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will be rejected until block is ended).

RowDescription (B)

Byte1('T')
Identifies the message as a row description.

Int32
Length of message contents in bytes, including self.

Int16
Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String
The field name.

Int32
If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16
If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32
The object ID of the field's data type.

Int16
The data type size (see `pg_type.typlen`). Note that negative values denote variable-width types.
Chapter 50. Frontend/Backend Protocol

Int32

The type modifier (see pg_attribute.atttypmod). The meaning of the modifier is type-specific.

Int16

The format code being used for the field. Currently will be zero (text) or one (binary). In a RowDescription returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32(8)

Length of message contents in bytes, including self.

Int32(80877103)

The SSL request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5679 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32

Length of message contents in bytes, including self.

Int32(196608)

The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).

The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. user is required, others are optional. Each parameter is specified as:

String

The parameter name. Currently recognized names are:

user

The database user name to connect as. Required; there is no default.

database

The database to connect to. Defaults to the user name.

options

Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (\); write \\ to represent a literal backslash.
In addition to the above, other parameters may be listed. Parameter names beginning with \_pq\_ are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

**String**

The parameter value.

**Sync (F)**

Byte1(‘S’)

Identifies the message as a Sync command.

Int32(4)

Length of message contents in bytes, including self.

**Terminate (F)**

Byte1(‘X’)

Identifies the message as a termination.

Int32(4)

Length of message contents in bytes, including self.

### 50.6. Error and Notice Message Fields

This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.

**S**

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

**C**

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

**M**

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.
Chapter 50. Frontend/Backend Protocol

D
Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

H
Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

P
Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

P
Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

q
Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

W
Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

s
Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

t
Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table’s schema.)

c
Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

D
Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type’s schema.)

n
Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren’t created with constraint syntax.)

F
File: the file name of the source-code location where the error was reported.
Chapter 50. Frontend/Backend Protocol

L
Line: the line number of the source-code location where the error was reported.

R
Routine: the name of the source-code routine reporting the error.

Note: The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

50.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the options field, but given the limited width of options and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that PasswordMessage now has a type byte.

ErrorResponse and NoticeResponse (’E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The ReadyForQuery (’Z’) message includes a transaction status indicator.

The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server’s internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and
will eventually be removed.) Binary Copy is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus ('s') messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription ('t') message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse ('p') message is no longer generated by the backend.

The NotificationResponse ('a') message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse ('i') message used to include an empty string parameter; this has been removed.
Chapter 51. PostgreSQL Coding Conventions

51.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of `if`, `while`, `switch`, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn’t mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments (`//` comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

```c
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by `pgindent`, but it will re-flow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```c
/******
 * comment text begins here
 * and continues here
 ******/
```

While submitted patches do not absolutely have to follow these formatting rules, it’s a good idea to do so. Your code will get run through `pgindent` before the next release, so there’s no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The `src/tools` directory contains sample settings files that can be used with the `emacs`, `xemacs` or `vim` editors to help ensure that they format code according to these conventions.

The text browsing tools `more` and `less` can be invoked as:

```
more -x4
less -x4
```

to make them show tabs appropriately.
51.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec’s SQLSTATE conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```c
ereport(ERROR,
    (errcode(ERRCODE_DIVISION_BY_ZERO),
     errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the SQLSTATE error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```c
ereport(ERROR,
    (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
     errmsg("function %s is not unique",
             func_signature_string(funcname, nargs, NIL, actual_arg_types)),
     errhint("Unable to choose a best candidate function. "
             "You might need to add explicit typecasts.")));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is `ERROR` or higher, `ereport` aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode(sqlerrcode)` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode()` call.

- `errmsg(const char *msg, ...)` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `printf`-style format codes. In addition to the standard format codes accepted by `printf`, the format code `%m` can be used to insert the error message identifier code as part of the message text.
returned by `strerror` for the current value of `errno`.\footnote{That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.} %m does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

- `errmsg_internal(const char *msg, ...)` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

- `errmsg_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 52.2.2.

- `errdetail(const char *msg, ...)` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

- `errdetail_internal(const char *msg, ...)` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- `errdetail_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 52.2.2.

- `errdetail_log(const char *msg, ...)` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

- `errdetail_log_plural(const char *fmt_singular, const char *fmt_plural, unsigned long n, ...)` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 52.2.2.

- `errhint(const char *msg, ...)` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

- `errcontext(const char *msg, ...)` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

- `errposition(int cursorpos)` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.
• errtable(Relation rel) specifies a relation whose name and schema name should be included as auxiliary fields in the error report.

• errtablecol(Relation rel, int attnum) specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.

• errtableconstraint(Relation rel, const char *conname) specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated pg_constraint entry. Be careful to pass the underlying heap relation, not the index itself, as rel.

• errdatatype(Oid datatypeOid) specifies a data type whose name and schema name should be included as auxiliary fields in the error report.

• errdomainconstraint(Oid datatypeOid, const char *conname) specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.

• errcode_for_file_access() is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved errno to determine which error code to generate. Usually this should be used in combination with %m in the primary error message text.

• errcode_for_socket_access() is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.

• errhidestmt(bool hide_stmt) can be called to specify suppression of the STATEMENT: portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

**Note:** At most one of the functions errtable, errtablecol, errtableconstraint, errdatatype, or errdomainconstraint should be used in an ereport call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it’s likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function elog that is still heavily used. An elog call:

```c
elog(level, "format string", ...);
```

is exactly equivalent to:

```c
ereport(level, (errmsg_internal("format string", ...)))
```

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, elog should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through ereport. Nonetheless, there are enough internal “cannot happen” error checks in the system that elog is still widely used; it is preferred for those messages for its notational simplicity.
Advice about writing good error messages can be found in Section 51.3.

51.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.

51.3.1. What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m
(plus a long addendum that is basically a hint)

write:

Primary: could not create shared memory segment: %m
Detail: Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint: the addendum

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users don’t know the details anyway.

51.3.2. Formatting

Don’t put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (\n) can be used to indicate suggested paragraph breaks. Don’t end a message with a newline. Don’t use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.
51.3.3. Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-internal technical issue that many users aren’t even familiar with, it won’t scale to other kinds of quoted terms, it doesn’t translate to other languages, and it’s pretty pointless, too.

51.3.4. Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don’t clutter messages with unnecessary or duplicate quote marks.

51.3.5. Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they’re long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there’s only one sentence.

51.3.6. Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.
Chapter 51. PostgreSQL Coding Conventions

Rationale: It's easier to make everything look more consistent this way, since some messages are complete sentences and some not.

51.3.7. Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don’t pretend otherwise.

51.3.8. Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

could not open file "%s": %m

and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn’t exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it’s conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

51.3.9. Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

51.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.
51.3.11. Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it’s unnatural if the embedded text is likely to be the most important part of the message, as is often the case.

51.3.12. Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD: could not open file %s
BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.

51.3.13. Function Names

Don’t include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it’s not helpful information. If the error text doesn’t make as much sense without the function name, reword it.

BAD: pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD: open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don’t know what all those functions do.

51.3.14. Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

Bad. Error messages like “bad result” are really hard to interpret intelligently. It’s better to write why the result is “bad”, e.g., “invalid format”.

Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it’s invalid.
Unknown. Try to avoid “unknown”. Consider “error: unknown response”. If you don’t know what the response is, how do you know it’s erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD: unknown node type
BETTER: unrecognized node type: 42

Find vs. Exists. If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn’t “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn’t “exist”. Using “find” in this case sounds weak and confuses the issue.

May vs. Can vs. Might. “May” suggests permission (e.g., ”You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., ”I can lift that log.”), and “might” suggests possibility (e.g., ”It might rain today.”). Using the proper word clarifies meaning and assists translation.

Contractions. Avoid contractions, like “can’t”; use “cannot” instead.

51.3.15. Proper Spelling
Spell out words in full. For instance, avoid:

• spec
• stats
• parens
• auth
• xact

Rationale: This will improve consistency.

51.3.16. Localization
Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 52.2.2 to avoid making life difficult for translators.
Chapter 52. Native Language Support

52.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

52.1.1. Requirements

We won’t judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the --enable-nls option. This will also check for the libintl library and the msgfmt program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs xgettext and msgmerge, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won’t need xgettext. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

52.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is to no surprise either .po or .mo. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are psql.po (PO file for psql) or fr.mo (MO file in French).

The file format of the PO files is illustrated here:

\[
\begin{array}{l}
\# \text{ comment} \\
\text{msgid "original string"} \\
\text{msgstr "translated string"}
\end{array}
\]
Chapter 52. Native Language Support

msgid "more original"
msgstr "another translated"
"string can be broken up like this"

...  

The msgid’s are extracted from the program source. (They need not be, but this is the most common way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the #. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The #: comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but he can if there is doubt about the correct translation. The #, comments contain flags that describe the message in some way. There are currently two flags: fuzzy is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is c-format, which indicates that the message is a printf-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the c-format flag.

52.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file nls.mk, then this program has been prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are named language.po, where language is the ISO 639-1 two-letter language code (in lower case)\(^1\), e.g., fr.po for French. If there is really a need for more than one translation effort per language then the files can also be named language_region.po where region is the ISO 3166-1 two-letter country code (in upper case)\(^2\), e.g., pt_BR.po for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

make init-po

2. http://www.iso.org/iso/country_names_and_code_elements
This will create a file `progname.pot` (`.pot` to distinguish it from PO files that are “in production”. The `T` stands for “template”. ) Copy this file to `language.po` and edit it. To make it known that the new language is available, also edit the file `nls.mk` and add the language (or language and country) code to the line that looks like:

```
AVAIL_LANGUAGES := de fr
```

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

```
make update-po
```

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a `.po.new` extension.

### 52.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the `msgstr` directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a `printf` format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:
  ```
  msgstr "Die Datei %2$s hat %1$u Zeichen."
  ```
  Then the first placeholder will actually use the second argument from the list. The `digits$` needs to follow the `%` immediately, before any other format manipulators. (This feature really exists in the `printf` family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)
- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.
- Maintain the style and tone of the original string. Specifically, messages that are not sentences (`cannot open file %s`) should probably not start with a capital letter (if your language distinguishes letter
52.2. For the Programmer

52.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```c
#ifdef ENABLE_NLS
#include <locale.h>
#endif
...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("proname", LOCALEDIR);
textdomain("proname");
#endif
(The proname can actually be chosen freely.)
```

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```c
fprintf(stderr, "panic level %d\n", lvl);
would be changed to:
```

```c
fprintf(stderr, gettext("panic level %d\n"), lvl);
(gettext is defined as a no-op if NLS support is not configured.)
```

This tends to add a lot of clutter. One common shortcut is to use:

```c
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:
Chapter 52. Native Language Support

CATALOG_NAME
The program name, as provided in the textdomain() call.

AVAIL_LANGUAGES
List of provided translations — initially empty.

GETTEXT_FILES
List of files that contain translatable strings, i.e., those marked with gettext or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a + and the second word be a file that contains one file name per line.

GETTEXT_TRIGGERS
The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only gettext() calls are known. If you used _ or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form func:2 (for the second argument). If you have a function that supports pluralized messages, the item should look like func:1,2 (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

52.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

• Do not construct sentences at run-time, like:

```c
printf("Files were %s.\n", flag ? "copied" : "removed");
```

The word order within the sentence might be different in other languages. Also, even if you remember to call gettext() on each fragment, the fragments might not translate well separately. It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

• For similar reasons, this won’t work:

```c
printf("copied %d file%s", n, n!=1 ? "s" : "");
```

because it assumes how the plural is formed. If you figured you could solve it like this:

```c
if (n==1)
   printf("copied 1 file");
else
   printf("copied %d files", n);
```

then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s often best to design the message to avoid the issue altogether, for instance like this:

```c
printf("number of copied files: %d", n);
```
If you really want to construct a properly pluralized message, there is support for this, but it’s a bit awkward. When generating a primary or detail error message in `ereport()`, you can write something like this:

```c
errmsg_plural("copied %d file",
             "copied %d files",
             n, n)
```

The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether `n` is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of `n`.

If you need to pluralize a message that isn’t going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the gettext documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

  ```c
  /* translator: This message is not what it seems to be. */
  ```

  These comments are copied to the message catalog files so that the translators can see them.
Chapter 53. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type `language_handler`. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 35.9.

The call handler is called in the same way as any other function: It receives a pointer to a `FunctionCallInfoData` struct containing argument values and information about the called function, and it is expected to return a Datum result (and possibly set the `isnull` field of the `FunctionCallInfoData` structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the `flinfo->fn_oid` field of the `FunctionCallInfoData` structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the `pg_proc` system catalog and to analyze the argument and return types of the called function. The `AS` clause from the `CREATE FUNCTION` command for the function will be found in the `prosrc` column of the `pg_proc` row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the `flinfo->fn_extra` field. This will initially be `NULL`, but can be set by the call handler to point at information about the called function. On subsequent calls, if `flinfo->fn_extra` is already non-NULL then it can be used and the information lookup step skipped. The call handler must make sure that `flinfo->fn_extra` is made to point at memory that will live at least until the end of the current query, since an `FmgrInfo` data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by `flinfo->fn_mcxt`; such data will normally have the same lifespan as the `FmgrInfo` itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the `FunctionCallInfoData`'s `context` field points at a `TriggerData` structure, rather than being `NULL` as it is in a plain function call. A language handler should provide mechanisms for procedural-
language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

```c
#include "postgres.h"
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
  Datum   retval;

  if (CALLED_AS_TRIGGER(fcinfo))
  {
    /*
      * Called as a trigger procedure
      */
    TriggerData  *trigdata = (TriggerData *) fcinfo->context;
    retval = ...;
  }
  else
  {
    /*
      * Called as a function
      */
    retval = ...
  }

  return retval;
}
```

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 35.9.6), the following commands then register the sample procedural language:

```sql
CREATE FUNCTION plsample_call_handler() RETURNS language_handler
  AS 'filename'
  LANGUAGE C;
CREATE LANGUAGE plsample
```
Although providing a call handler is sufficient to create a minimal procedural language, there are two
other functions that can optionally be provided to make the language more convenient to use. These are
a validator and an inline handler. A validator can be provided to allow language-specific checking to be
done during CREATE FUNCTION. An inline handler can be provided to allow the language to support
anonymous code blocks executed via the DO command.

If a validator is provided by a procedural language, it must be declared as a function taking a single
parameter of type oid. The validator’s result is ignored, so it is customarily declared to return void. The
validator will be called at the end of a CREATE FUNCTION command that has created or updated a
function written in the procedural language. The passed-in OID is the OID of the function’s pg_proc row.
The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call
CheckFunctionValidatorAccess() to diagnose explicit calls to the validator that the user could not
achieve through CREATE FUNCTION. Typical checks then include verifying that the function’s argument
and result types are supported by the language, and that the function’s body is syntactically correct in
the language. If the validator finds the function to be okay, it should just return. If it finds an error, it
should report that via the normal ereport() error reporting mechanism. Throwing an error will force a
transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the check_function_bodies parameter: if it is turned off then
any expensive or context-sensitive checking should be skipped. If the language provides for code ex-
ecution at compilation time, the validator must suppress checks that would induce such execution. In
particular, this parameter is turned off by pg_dump so that it can load procedural language functions
without worrying about side effects or dependencies of the function bodies on other database objects.
(Because of this requirement, the call handler should avoid assuming that the validator has fully checked
the function. The point of having a validator is not to let the call handler omit checks, but to notify the
user immediately if there are obvious errors in a CREATE FUNCTION command.) While the choice of
exactly what to check is mostly left to the discretion of the validator function, note that the core CREATE
FUNCTION code only executes SET clauses attached to a function when check_function_bodies is
on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped
when check_function_bodies is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a
single parameter of type internal. The inline handler’s result is ignored, so it is customarily declared to
return void. The inline handler will be called when a DO statement is executed specifying the procedural
language. The parameter actually passed is a pointer to an InlineCodeBlock struct, which contains
information about the DO statement’s parameters, in particular the text of the anonymous code block to be
executed. The inline handler should execute this code and return.

It’s recommended that you wrap all these function declarations, as well as the CREATE LANGUAGE com-
mmand itself, into an extension so that a simple CREATE EXTENSION command is sufficient to install the
language. See Section 35.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write
your own language handler. Look into the src/pl subdirectory of the source tree. The CREATE LAN-
GUAGE reference page also has some useful details.
Chapter 54. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note: The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn’t gained wide adoption anyway.

54.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 35.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type fdw_handler. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 54.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either ForeignDataWrapperRelationId, ForeignServerRelationId, UserMappingRelationId, or ForeignTableRelationId). If no validator function is supplied, options are not checked at object creation time or object alteration time.

54.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc’d FdwRoutine struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.
The `FdwRoutine` struct type is declared in `src/include/foreign/fdwapi.h`, which see for additional details.

### 54.2.1. FDW Routines For Scanning Foreign Tables

```c
void GetForeignRelSize (PlannerInfo *root,
                       RelOptInfo *baserel,
                       Oid foreigntableid);
```

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. `root` is the planner’s global information about the query; `baserel` is the planner’s information about this table; and `foreigntableid` is the `pg_class` OID of the foreign table. (`foreigntableid` could be obtained from the planner data structures, but it’s passed explicitly to save effort.)

This function should update `baserel->rows` to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of `baserel->rows` is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update `baserel->width` if it can compute a better estimate of the average result row width.

See Section 54.4 for additional information.

```c
void GetForeignPaths (PlannerInfo *root,
                      RelOptInfo *baserel,
                      Oid foreigntableid);
```

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for `GetForeignRelSize`, which has already been called.

This function must generate at least one access path (`ForeignPath` node) for a scan on the foreign table and must call `add_path` to add each such path to `baserel->pathlist`. It’s recommended to use `create_foreignscan_path` to build the `ForeignPath` nodes. The function can generate multiple access paths, e.g., a path which has valid `pathkeys` to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 54.4 for additional information.

```c
ForeignScan * GetForeignPlan (PlannerInfo *root,
                               RelOptInfo *baserel,
                               Oid foreigntableid,
                               ForeignPath *best_path,
                               List *tlist,
                               List *scan_clauses,
                               Plan *outer_plan);
```

Create a `ForeignScan` plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for `GetForeignRelSize`, plus the selected `ForeignPath` (previously
produced by `GetForeignPaths` or `GetForeignJoinPaths`), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the `ForeignScan`, which is used for rechecks performed by `RecheckForeignScan`. (If the path is for a join rather than a base relation, `foreigntableid` is `InvalidOid`.)

This function must create and return a `ForeignScan` plan node; it’s recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 54.4 for additional information.

```c
void
BeginForeignScan (ForeignScanState *node, int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still NULL. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor’s operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```c
TupleTableSlot *
IterateForeignScan (ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node’s `ScanTupleSlot` should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node’s `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that PostgreSQL’s executor doesn’t care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```c
void
ReScanForeignScan (ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.
EndForeignScan (ForeignScanState *node);

End the scan and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

### 54.2.2. FDW Routines For Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables’ data and doing the join locally), it should provide this callback function:

```c
void
GetForeignJoinPaths (PlannerInfo *root,
                     RelOptInfo *joinrel,
                     RelOptInfo *outerrel,
                     RelOptInfo *innerrel,
                     JoinType jointype,
                     JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with GetForeignPaths, this function should generate ForeignPath path(s) for the supplied joinrel, and call add_path to add these paths to the set of paths considered for the join. But unlike GetForeignPaths, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a ForeignPath path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the scanrelid of the resulting ForeignScan plan node should be set to zero, since there is no single relation that it represents; instead, the fs_relids field of the ForeignScan node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill fdw_scan_tlist with an appropriate list of TargetEntry nodes, representing the set of columns it will supply at run time in the tuples it returns.

See Section 54.4 for additional information.

### 54.2.3. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```c
void
AddForeignUpdateTargets (Query *parsetree,
                        RangeTblEntry *target_rte,
                        Relation target_relation);
```

2163
UPDATE and DELETE operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an UPDATE or DELETE.

To do that, add TargetEntry items to parsetree->targetList, containing expressions for the extra values to be fetched. Each such entry must be marked resjunk = true, and must have a distinct resname that will identify it at execution time. Avoid using names matching ctidN, wholerow, or wholerowN, as the core system can generate junk columns of these names. If the extra expressions are more complex than simple Vars, they must be run through eval_const_expressions before adding them to the targetlist.

Although this function is called during planning, the information provided is a bit different from that available to other planning routines. parsetree is the parse tree for the UPDATE or DELETE command, while target_rte and target_relation describe the target foreign table.

If the AddForeignUpdateTargets pointer is set to NULL, no extra target expressions are added. (This will make it impossible to implement DELETE operations, though UPDATE may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```c
List *
PlanForeignModify (PlannerInfo *root,
    ModifyTable *plan,
    Index resultRelation,
    int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the ModifyTable plan node that performs the update action. This private information must have the form of a List, and will be delivered to BeginForeignModify during the execution stage.

root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into plan->plans or other substructure of the plan node.

See Section 54.4 for additional information.

If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

```c
void
BeginForeignModify (ModifyTableState *mtstate,
    ResultRelInfo *rinfo,
    List *fdw_private,
    int subplan_index,
    int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert, ExecForeignUpdate or ExecForeignDelete will be called for each tuple to be inserted, updated, or deleted.
mtstate is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. rinfo is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) fdw_private contains the private data generated by PlanForeignModify, if any. subplan_index identifies which target of the ModifyTable plan node this is. eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.

TupleTableSlot *
ExecForeignInsert (EState *estate,
ResultRelInfo *rinfo,
TupleTableSlot *slot,
TupleTableSlot *planSlot);

Insert one tuple into the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the tuple to be inserted; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. (The planSlot is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the INSERT query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the ExecForeignInsert pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

TupleTableSlot *
ExecForeignUpdate (EState *estate,
ResultRelInfo *rinfo,
TupleTableSlot *slot,
TupleTableSlot *planSlot);

Update one tuple in the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the new data for the tuple; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. In particular, any junk columns that were requested by AddForeignUpdateTargets will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.
The data in the returned slot is used only if the `UPDATE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to `NULL`, attempts to update the foreign table will fail with an error message.

```c
TupleTableSlot *
ExecForeignDelete (EState *estate,
                ResultRelInfo *rinfo,
                TupleTableSlot *slot,
                TupleTableSlot *planSlot);
```

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node’s subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or `NULL` if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to `NULL`, attempts to delete from the foreign table will fail with an error message.

```c
void
EndForeignModify (EState *estate,
                  ResultRelInfo *rinfo);
```

End the table update and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

```c
int
IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is, `(1 << CMD_UPDATE) = 4` for `UPDATE`, `(1 << CMD_INSERT) = 8` for `INSERT`, and `(1 << CMD_DELETE) = 16` for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it’s permissible to throw an error in the execution...
routine instead of checking in this function. However, this function is used to determine updatability for display in the information_schema views.)

54.2.4. FDW Routines For Row Locking
If an FDW wishes to support late row locking (as described in Section 54.5), it must provide the following callback functions:

RowMarkType
GetForeignRowMarkType (RangeTblEntry *rte, LockClauseStrength strength);

Report which row-marking option to use for a foreign table. rte is the RangeTblEntry node for the table and strength describes the lock strength requested by the relevant FOR UPDATE/SHARE clause, if any. The result must be a member of the RowMarkType enum type.

This function is called during query planning for each foreign table that appears in an UPDATE, DELETE, or SELECT FOR UPDATE/SHARE query and is not the target of UPDATE or DELETE.

If the GetForeignRowMarkType pointer is set to NULL, the ROW_MARK_COPY option is always used.
(This implies that RefetchForeignRow will never be called, so it need not be provided either.)

See Section 54.5 for more information.

HeapTuple
RefetchForeignRow (EState *estate, ExecRowMark *erm, Datum rowid, bool *updated);

Re-fetch one tuple from the foreign table, after locking it if required. estate is global execution state for the query.  erm is the ExecRowMark struct describing the target foreign table and the row lock type (if any) to acquire. rowid identifies the tuple to be fetched. updated is an output parameter.

This function should return a palloc’ed copy of the fetched tuple, or NULL if the row lock couldn’t be obtained. The row lock type to acquire is defined by erm->markType, which is the value previously returned by GetForeignRowMarkType. (ROW_MARK_REFERENCE means to just re-fetch the tuple without acquiring any lock, and ROW_MARK_COPY will never be seen by this routine.)

In addition, *updated should be set to true if what was fetched was an updated version of the tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always returning true is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; a NULL return is only appropriate if the SKIP LOCKED option is specified by erm->waitPolicy.

The rowid is the ctid value previously read for the row to be re-fetched. Although the rowid value is passed as a Datum, it can currently only be a tid. The function API is chosen in hopes that it may be possible to allow other data types for row IDs in future.

If the RefetchForeignRow pointer is set to NULL, attempts to re-fetch rows will fail with an error message.
Chapter 54. Writing A Foreign Data Wrapper

See Section 54.5 for more information.

```c
bool
RecheckForeignScan (ForeignScanState *node, TupleTableSlot *slot);
```

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly provide a modified version of the tuple. For foreign data wrappers which do not perform join pushdown, it will typically be more convenient to set this to NULL and instead set fdw_recheck_quals appropriately. When outer joins are pushed down, however, it isn’t sufficient to reapply the checks relevant to all the base tables to the result tuple, even if all needed attributes are present, because failure to match some qualifier might result in some attributes going to NULL, rather than in no tuple being returned. RecheckForeignScan can recheck qualifiers and return true if they are still satisfied and false otherwise, but it can also store a replacement tuple into the supplied slot.

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the ForeignScan. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops.

### 54.2.5. FDW Routines for EXPLAIN

```c
void
ExplainForeignScan (ForeignScanState *node,
                     ExplainState *es);
```

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.

```c
void
ExplainForeignModify (ModifyTableState *mtstate,
                       ResultRelInfo *rinfo,
                       List *fdw_private,
                       int subplan_index,
                       struct ExplainState *es);
```

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.
54.2.6. FDW Routines for ANALYZE

bool
AnalyzeForeignTable (Relation relation,
    AcquireSampleRowsFunc *func,
    BlockNumber *totalpages);

This function is called when ANALYZE is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return true, and provide a pointer to a function that will collect sample rows from the table in func, plus the estimated size of the table in pages in totalpages. Otherwise, return false.

If the FDW does not support collecting statistics for any tables, the AnalyzeForeignTable pointer can be set to NULL.

If provided, the sample collection function must have the signature

int
AcquireSampleRowsFunc (Relation relation, int elevel,
    HeapTuple *rows, int targrows,
    double *totalrows,
    double *totaldeadrows);

A random sample of up to targrows rows should be collected from the table and stored into the caller-provided rows array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters totalrows and totaldeadrows. (Set totaldeadrows to zero if the FDW does not have any concept of dead rows.)

54.2.7. FDW Routines For IMPORT FOREIGN SCHEMA

List *
ImportForeignSchema (ImportForeignSchemaStmt *stmt, Oid serverOid);

Obtain a list of foreign table creation commands. This function is called when executing IMPORT FOREIGN SCHEMA, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a CREATE FOREIGN TABLE command. These strings will be parsed and executed by the core server.

Within the ImportForeignSchemaStmt struct, remote_schema is the name of the remote schema from which tables are to be imported. list_type identifies how to filter table names: FDW_IMPORT_SCHEMA_ALL means that all tables in the remote schema should be imported (in this case table_list is empty), FDW_IMPORT_SCHEMA_LIMIT_TO means to include only tables listed in table_list, and FDW_IMPORT_SCHEMA_EXCEPT means to exclude the tables listed in table_list. options is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the NOT NULL attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the local_schema field of the ImportForeignSchemaStmt, because the core server will automatically insert that name into the parsed CREATE FOREIGN TABLE commands.
Chapter 54. Writing A Foreign Data Wrapper

The FDW does not have to concern itself with implementing the filtering specified by list_type and table_list, either, as the core server will automatically skip any returned commands for tables excluded according to those options. However, it’s often useful to avoid the work of creating commands for excluded tables in the first place. The function IsImportableForeignTable() may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the ImportForeignSchema pointer can be set to NULL.

54.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file foreign/foreign.h in your source file. That header also defines the struct types that are returned by these functions.

ForeignDataWrapper * GetForeignDataWrapper(Oid fdwid);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given OID. A ForeignDataWrapper object contains properties of the FDW (see foreign/foreign.h for details).

ForeignServer * GetForeignServer(Oid serverid);

This function returns a ForeignServer object for the foreign server with the given OID. A ForeignServer object contains properties of the server (see foreign/foreign.h for details).

UserMapping * GetUserMapping(Oid userid, Oid serverid);

This function returns a UserMapping object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for PUBLIC, or throw error if there is none.) A UserMapping object contains properties of the user mapping (see foreign/foreign.h for details).

ForeignTable * GetForeignTable(Oid relid);

This function returns a ForeignTable object for the foreign table with the given OID. A ForeignTable object contains properties of the foreign table (see foreign/foreign.h for details).

List * GetForeignColumnOptions(Oid relid, AttrNumber attnum);

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of DefElem. NIL is returned if the column has no options.
Some object types have name-based lookup functions in addition to the OID-based ones:

```c
ForeignDataWrapper * GetForeignDataWrapperByName(const char *name, bool missing_ok);
```

This function returns a `ForeignDataWrapper` object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if `missing_ok` is true, otherwise raise an error.

```c
ForeignServer * GetForeignServerByName(const char *name, bool missing_ok);
```

This function returns a `ForeignServer` object for the foreign server with the given name. If the server is not found, return NULL if `missing_ok` is true, otherwise raise an error.

### 54.4. Foreign Data Wrapper Query Planning

The FDW callback functions `GetForeignRelSize`, `GetForeignPaths`, `GetForeignPlan`, `PlanForeignModify`, and `GetForeignJoinPaths` must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in `root` and `baserel` can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). `baserel->baserestrictinfo` is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) `baserel->reltargetlist` can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the `ForeignScan` plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be `palloc`d, so that it will be reclaimed at the end of planning.

`baserel->fdw_private` is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the `RelOptInfo` node is created. It is useful for passing information forward from `GetForeignRelSize` to `GetForeignPaths` and/or `GetForeignPaths` to `GetForeignPlan`, thereby avoiding recalculation.

`GetForeignPaths` can identify the meaning of different access paths by storing private information in the `fdw_private` field of `ForeignPath` nodes. `fdw_private` is declared as a List pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that’s dumpable by `nodeToString`, for use with debugging support available in the backend.

`GetForeignPlan` can examine the `fdw_private` field of the selected `ForeignPath` node, and can generate `fdw_exprs` and `fdw_private` lists to be placed in the `ForeignScan` plan node, where they will be available at execution time. Both of these lists must be represented in a form that `copyObject` knows how to copy. The `fdw_private` list has no other restrictions and is not interpreted by the core backend in any way. The `fdw_exprs` list, if not NIL, is expected to contain expression trees that are
Chapter 54. Writing A Foreign Data Wrapper

intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The passed scan_clauses list contains the same clauses as baserel->baserestrictinfo, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip RestrictInfo nodes from the scan_clauses list (using extract_actual_clauses) and put all the clauses into the plan node’s qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node’s qual list so that the executor doesn’t waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form foreign_variable = sub_expression, which it determines can be executed on the remote server given the locally-evaluated value of the sub_expression. The actual identification of such a clause should happen during GetForeignPaths, since it would affect the cost estimate for the path. The path’s fdw_private field would probably include a pointer to the identified clause’s RestrictInfo node. Then GetForeignPlan would remove that clause from scan_clauses, but add the sub_expression to fdw_exprs to ensure that it gets massaged into executable form. It would probably also put control information into the plan node’s fdw_private field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve something like WHERE foreign_variable = $1, with the parameter value obtained at run time from evaluation of the fdw_exprs expression tree.

Any clauses removed from the plan node’s qual list must instead be added to fdw_recheck_quals or rechecked by RecheckForeignScan in order to ensure correct behavior at the READ COMMITTED isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using fdw_recheck_quals is typically easier than implementing checks inside RecheckForeignScan, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to NULL without rejecting the tuple entirely.

Another ForeignScan field that can be filled by FDWs is fdw_scan_tlist, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to NIL, implying that the returned tuples have the row type declared for the foreign table. A non-NIL value must be a target list (list of TargetEntry) containing Vars and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won’t be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to fdw_scan_tlist. Note that join plans (created from paths made by GetForeignJoinPaths) must always supply fdw_scan_tlist to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table’s restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example foreign_variable = local_variable. Such clauses will not be found in baserel->baserestrictinfo but must be sought in the relation’s join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of param_info; use get_baserel_parampathinfo to compute that value. In GetForeignPlan, the local_variable portion of the join clause would be added to fdw_exprs, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, GetForeignJoinPaths should produce ForeignPaths for potential
Chapter 54. Writing A Foreign Data Wrapper

remote joins in much the same way as GetForeignPaths works for base tables. Information about the intended join can be passed forward to GetForeignPlan in the same ways described above. However, baserestrictinfo is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to GetForeignJoinPaths as a separate parameter (extra->restrictlist).

When planning an UPDATE or DELETE, PlanForeignModify can look up the RelOptInfo struct for the foreign table and make use of the baserel->fdw_private data previously created by the scan-planning functions. However, in INSERT the target table is not scanned so there is no RelOptInfo for it. The List returned by PlanForeignModify has the same restrictions as the fdw_private list of a ForeignScan plan node, that is it must contain only structures that copyObject knows how to copy.

INSERT with an ON CONFLICT clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that ON CONFLICT DO UPDATE is not supported, since the specification is mandatory there.

54.5. Row Locking in Foreign Data Wrappers

If an FDW’s underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary PostgreSQL tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform early locking or late locking. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as PostgreSQL TIDs do.

By default, PostgreSQL ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 54.2.4, which were added in PostgreSQL 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in READ COMMITTED isolation mode, PostgreSQL may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard PostgreSQL tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an UPDATE or DELETE on a foreign table, it is recommended that the ForeignScan operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of SELECT FOR UPDATE. An FDW can detect whether a table is an UPDATE/DELETE target at plan
time by comparing its relid to root->parse->resultRelation, or at execution time by using ExecRelationIsTargetRelation(). An alternative possibility is to perform late locking within the ExecForeignUpdate or ExecForeignDelete callback, but no special support is provided for this.

For foreign tables that are specified to be locked by a SELECT FOR UPDATE/SHARE command, the ForeignScan operation can again perform early locking by fetching tuples with the equivalent of SELECT FOR UPDATE/SHARE. To perform late locking instead, provide the callback functions defined in Section 54.2.4. In GetForeignRowMarkType, select rowmark option ROW_MARK_EXCLUSIVE, ROW_MARK_NOKEYEXCLUSIVE, ROW_MARK_SHARE, or ROW_MARK_KEYSHARE depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using get_plan_rowmark at plan time, or ExecFindRowMark at execution time; you must check not only whether a non-null rowmark struct is returned, but that its strength field is not LCS_NONE.

Lastly, for foreign tables that are used in an UPDATE, DELETE or SELECT FOR UPDATE/SHARE command but are not specified to be row-locked, you can override the default choice to copy entire rows by having GetForeignRowMarkType select option ROW_MARK_REFERENCE when it sees lock strength LCS_NONE. This will cause RefetchForeignRow to be called with that value for markType; it should then re-fetch the row without acquiring any new lock. (If you have a GetForeignRowMarkType function but don’t wish to re-fetch unlocked rows, select option ROW_MARK_COPY for LCS_NONE.)

See src/include/nodes/lockoptions.h, the comments for RowMarkType and PlanRowMark in src/include/nodes/plannodes.h, and the comments for ExecRowMark in src/include/nodes/execnodes.h for additional information.
Chapter 55. Writing A Table Sampling Method

PostgreSQL’s implementation of the TABLESAMPLE clause supports custom table sampling methods, in addition to the BERNOULLI and SYSTEM methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the TABLESAMPLE clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the TABLESAMPLE clause. The internal argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a palloc’d struct of type TsmRoutine, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 55.1.

In addition to function pointers, the TsmRoutine struct must provide these additional fields:

```
List *parameterTypes
```

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the TABLESAMPLE clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value FLOAT4OID, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

```
bool repeatable_across_queries
```

If true, the sampling method can deliver identical samples across successive queries, if the same parameters and REPEATABLE seed value are supplied each time and the table contents have not changed. When this is false, the REPEATABLE clause is not accepted for use with the sampling method.

```
bool repeatable_across_scans
```

If true, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is false, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The TsmRoutine struct type is declared in src/include/access/tsmapi.h, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the src/backend/access/tablesample subdirectory of the source tree for the built-in sampling methods, and into the contrib subdirectory for add-on methods.
Chapter 55. Writing A Table Sampling Method

55.1. Sampling Method Support Functions

The TSM handler function returns a palloc’d TsmRoutine struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those pointers can be NULL.

```c
void
SampleScanGetSampleSize (PlannerInfo *root,
    RelOptInfo *baserel,
    List *paramexprs,
    BlockNumber *pages,
    double *tuples);
```

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the baserel->pages and baserel->tuples numbers by that, being sure to round the results to integral values.) The `paramexprs` list holds the expression(s) that are parameters to the TABLESAMPLE clause. It is recommended to use `estimate_expression_value()` to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they’re only estimates of what the run-time values will be). The `pages` and `tuples` parameters are outputs.

```c
void
InitSampleScan (SampleScanState *node,
    int eflags);
```

Initialize for execution of a SampleScan plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The SampleScanState node has already been created, but its tsm_state field is NULL. The InitSampleScan function can palloc whatever internal state data is needed by the sampling method, and store a pointer to it in node->tsm_state. Information about the table to scan is accessible through other fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is not set up yet). eflags contains flag bits describing the executor’s operating mode for this plan node.

When `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for EXPLAIN and EndSampleScan.

This function can be omitted (set the pointer to NULL), in which case BeginSampleScan must perform all initialization needed by the sampling method.

```c
void
BeginSampleScan (SampleScanState *node,
    Datum *params,
    int nparams,
    uint32 seed);
```

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is
not set up yet). The params array, of length nparams, contains the values of the parameters supplied in the TABLESAMPLE clause. These will have the number and types specified in the sampling method’s parameterTypes list, and have been checked to not be null. seed contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the REPEATABLE value if one was given, or the result of random() if not.

This function may adjust the fields node->use_bulkread and node->use_pagemode. If node->use_bulkread is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table’s pages. If node->use_pagemode is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked repeatable_across_scans, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of BeginSampleScan must lead to selecting the same tuples as before (if the TABLESAMPLE parameters and seed don’t change).

```
BlockNumber
NextSampleBlock (SampleScanState *node);
```

Returns the block number of the next page to be scanned, or InvalidBlockNumber if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```
OffsetNumber
NextSampleTuple (SampleScanState *node,
                   BlockNumber blockno,
                   OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or InvalidOffsetNumber if no tuples remain to be sampled. maxoffset is the largest offset number in use on the page.

**Note:** NextSampleTuple is not explicitly told which of the offset numbers in the range 1 .. maxoffset actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can examine node->ss.ss_currentScanDesc->rs_vistuples[] to identify which tuples are valid and visible. (This requires node->use_pagemode to be true.)

**Note:** NextSampleTuple must not assume that blockno is the same page number returned by the most recent NextSampleBlock call. It was returned by some previous NextSampleBlock call, but the core code is allowed to call NextSampleBlock in advance of actually scanning pages, so as
to support prefetching. It is OK to assume that once sampling of a given page begins, successive
NextSampleTuple calls all refer to the same page until InvalidOffsetNumber is returned.

```c
void EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release palloc’d memory, but any
eexternally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL)
in the common case where no such resources exist.
Chapter 56. Writing A Custom Scan Provider

PostgreSQL supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

56.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated what it believes to be the complete and correct set of access paths for the relation.

```
typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root, RelOptInfo *rel, Index rti, RangeTblEntry *rte);
extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;
```

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating `CustomPath` objects and adding them to `rel` using `add_path`. The custom scan provider is responsible for initializing the `CustomPath` object, which is declared like this:

```
typedef struct CustomPath
{
    Path     path;
    uint32   flags;
    List     *custom_paths;
    List     *custom_private;
    const CustomPathMethods *methods;
} CustomPath;
```

`path` must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. `flags` is a bit mask, which should include...
CUSTOMPATH_SUPPORT_BACKWARD_SCAN if the custom path can support a backward scan and CUSTOMPATH_SUPPORT_MARK_RESTORE if it can support mark and restore. Both capabilities are optional. An optional custom_paths is a list of Path nodes used by this custom-path node; these will be transformed into Plan nodes by planner. custom_private can be used to store the custom path’s private data. Private data should be stored in a form that can be handled by nodeToString, so that debugging routines that attempt to print the custom path will work as designed. methods must point to a (usually statically allocated) object implementing the required custom path methods, of which there are currently only two, as further detailed below.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create CustomPath path(s) for the join relation.

typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
   RelOptInfo *joinrel,
   RelOptInfo *outerrel,
   RelOptInfo *innerrel,
   JoinType jointype,
   JoinPathExtraData *extra);

extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

### 56.1.1. Custom Scan Path Callbacks

Plan *(*PlanCustomPath) (PlannerInfo *root,
   RelOptInfo *rel,
   CustomPath *best_path,
   List *tlist,
   List *clauses,
   List *custom_plans);

Convert a custom path to a finished plan. The return value will generally be a CustomScan object, which the callback must allocate and initialize. See Section 56.2 for more details.

void (*TextOutCustomPath) (StringInfo str,
   const CustomPath *node);

Generate additional output when nodeToString is invoked on this custom path. This callback is optional. Since nodeToString will automatically dump all fields in the structure that it can see, including custom_private, this is only useful if the CustomPath is actually embedded in a larger struct containing additional fields.
### 56.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```c
typedef struct CustomScan {
    Scan      scan;
    uint32    flags;
    List      *custom_plans;
    List      *custom_exprs;
    List      *custom_private;
    List      *custom_scan_tlist;
    Bitmapset *custom_relids;
    const CustomScanMethods *methods;
} CustomScan;
```

- `scan` must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. `flags` is a bit mask with the same meaning as in `CustomPath`. `custom_plans` can be used to store child Plan nodes. `custom_exprs` should be used to store expression trees that will need to be fixed up by `setrefs.c` and `subselect.c`, while `custom_private` should be used to store other private data that is only used by the custom scan provider itself. `custom_scan_tlist` can be NIL when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation’s row type. Otherwise it is a target list describing the actual scan tuples. `custom_scan_tlist` must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. `custom_relids` is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. `methods` must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a `CustomScan` scans a single relation, `scan.scanrelid` must be the range table index of the table to be scanned. When it replaces a join, `scan.scanrelid` should be zero.

Plan trees must be able to be duplicated using `copyObject`, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a `CustomScan` for the structure itself, as would be possible for a `CustomPath` or `CustomScanState`.

#### 56.2.1. Custom Scan Plan Callbacks

```c
Node *(*CreateCustomScanState) (CustomScan *cscan);
```

Allocate a `CustomScanState` for this `CustomScan`. The actual allocation will often be larger than required for an ordinary `CustomScanState`, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and `methods` set appropriately, but other fields should be left as zeroes at this stage; after `ExecInitCustomScan` performs basic initialization, the `BeginCustomScan` callback will be invoked to give the custom scan provider a chance to do whatever else is needed.
void (*TextOutCustomScan) (StringInfo str, const CustomScan *node);

Generate additional output when nodeToString is invoked on this custom plan node. This callback is optional. Since nodeToString will automatically dump all fields in the structure, including the substructure of the “custom” fields, there is usually not much need for this callback.

56.3. Executing Custom Scans

When a CustomScan is executed, its execution state is represented by a CustomScanState, which is declared as follows:

typedef struct CustomScanState
{
    ScanState ss;
    uint32 flags;
    const CustomExecMethods *methods;
} CustomScanState;

ss is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, ss.ss_currentRelation is left NULL. flags is a bit mask with the same meaning as in CustomPath and CustomScan. methods must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a CustomScanState, which need not support copyObject, will actually be a larger structure embedding the above as its first member.

56.3.1. Custom Scan Execution Callbacks

void (*BeginCustomScan) (CustomScanState *node, EState *estate, int eflags);

Complete initialization of the supplied CustomScanState. Standard fields have been initialized by ExecInitCustomScan, but any private fields should be initialized here.

TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);

Fetch the next scan tuple. If any tuples remain, it should fill ps_ResultTupleSlot with the next tuple in the current scan direction, and then return the tuple slot. If not, NULL or an empty slot should be returned.

void (*EndCustomScan) (CustomScanState *node);

Clean up any private data associated with the CustomScanState. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

void (*ReScanCustomScan) (CustomScanState *node);
Rewind the current scan to the beginning and prepare to rescan the relation.

```c
#include <customscan.h>

void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```c
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```c
void (*ExplainCustomScan) (CustomScanState *node,
                          List *ancestors,
                          ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.
57.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the join. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of join methods (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of indexes (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a near-exhaustive search over the space of alternative strategies. This algorithm, first introduced in IBM’s System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a genetic algorithm to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

57.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a population of individuals. The degree of adaptation of an individual to its environment is specified by its fitness.

The coordinates of an individual in the search space are represented by chromosomes, in essence a set of character strings. A gene is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be binary or integer.
Chapter 57. Genetic Query Optimizer

Through simulation of the evolutionary operations recombination, mutation, and selection new generations of search points are found that show a higher average fitness than their ancestors.

According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

Figure 57-1. Structured Diagram of a Genetic Algorithm

```

| | +-------------------------------------+
| | t := t + 1
| +=========================================+
```

57.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```
/\  2
/\  3
4  1
```

is encoded by the integer string '4-1-3-2', which means, first join relation '4' and '1', then '3', and then '2', where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:
• Usage of a steady state GA (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
• Usage of edge recombination crossover which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
• Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

57.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current geqo_seed parameter setting. As long as geqo_seed and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing geqo_seed.

57.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file src/backend/optimizer/geqo/geqo_main.c, routines gimme_pool_size and gimme_number_generations, we have to find a compromise for the parameter settings to satisfy two competing demands:

• Optimality of the query plan
• Computing time
In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.

At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

### 57.4. Further Reading

Chapter 58. Index Access Method Interface

Definition

This chapter defines the interface between the core PostgreSQL system and index access methods, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as secondary indexes; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical relation and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 63.6, and they all use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to tuple identifiers, or TIDs, of row versions (tuples) in the index’s parent table. A TID consists of a block number and an item number within that block (see Section 63.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

58.1. Catalog Entries for Indexes

Each index access method is described by a row in the `pg_am` system catalog (see Section 49.3). The principal contents of a `pg_am` row are references to `pg_proc` entries that identify the index access functions supplied by the access method. The APIs for these functions are defined later in this chapter. In addition, the `pg_am` row specifies a few fixed properties of the access method, such as whether it can support multi-column indexes. There is not currently any special support for creating or deleting `pg_am` entries; anyone able to write a new access method is expected to be competent to insert an appropriate row for themselves.

To be useful, an index access method must also have one or more operator families and operator classes defined in `pg_opfamily`, `pg_opclass`, `pg_amop`, and `pg_amproc`. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access method. Operator families and classes are described in Section 35.14, which is prerequisite material for reading this chapter.

An individual index is defined by a `pg_class` entry that describes it as a physical relation, plus a `pg_index` entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is al-
ways handed precomputed key values) but it will be very interested in the operator class information in pg_index. Both of these catalog entries can be accessed as part of the Relation data structure that is passed to all operations on the index.

Some of the flag columns of pg_am have nonobvious implications. The requirements of amcanunique are discussed in Section 58.5. The amcanmulticol flag asserts that the access method supports multicolumn indexes, while amoptionalkey asserts that it allows scans where no indexable restriction clause is given for the first index column. When amcanmulticol is false, amoptionalkey essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns must support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting amoptionalkey false. One reason that an index AM might set amoptionalkey false is if it doesn’t index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have amoptionalkey true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns must support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with WHERE a = 4. The system will assume the index can be used to scan for rows with a = 4, which is wrong if the index omits rows where b is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set amsearchnulls, indicating that it supports IS NULL and IS NOT NULL clauses as search conditions.

58.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide are:

IndexBuildResult *
ambuild (Relation heapRelation,
Relation indexRelation,
IndexInfo *indexInfo);

void
ambuildempty (Relation indexRelation);

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the ambuild function will call IndexBuildHeapScan() to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc’d struct containing statistics about the new index.

void
ambuildempty (Relation indexRelation);

Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This method is called only for unlogged tables; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.
Chapter 58. Index Access Method Interface Definition

aminsert (Relation indexRelation,
    Datum *values,
    bool *isnull,
    ItemPointer heap_tid,
    Relation heapRelation,
    IndexUniqueCheck checkUnique);

Insert a new tuple into an existing index. The values and isnull arrays give the key values to be indexed, and heap_tid is the TID to be indexed. If the access method supports unique indexes (its pg_am.amcanunique flag is true) then checkUnique indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 58.5 for details. Normally the access method only needs the heapRelation parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function’s Boolean result value is significant only when checkUnique is UNIQUE_CHECK_PARTIAL. In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, aminsert should just return without doing anything.

IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
    IndexBulkDeleteResult *stats,
    IndexBulkDeleteCallback callback,
    void *callback_state);

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in callback function must be called, in the style callback(TID, callback_state) returns bool, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to amvacuumcleanup.

Because of limited maintenance_work_mem, ambulkdelete might need to be called more than once when many tuples are to be deleted. The stats argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, ambulkdelete will modify and return the same struct if the passed stats is not null.

IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
    IndexBulkDeleteResult *stats);

Clean up after a VACUUM operation (zero or more ambulkdelete calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. stats is whatever the last ambulkdelete call returned, or NULL if ambulkdelete was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d struct. The statistics it contains will be used to update pg_class, and will be reported by VACUUM if VERBOSE is given. It is
OK to return NULL if the index was not changed at all during the VACUUM operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, amvacuumcleanup will also be called at completion of an ANALYZE operation. In this case stats is always NULL and any return value will be ignored. This case can be distinguished by checking info->analyze_only. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```c
bool amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support index-only scans on the given column, by returning the indexed column values for an index entry in the form of an IndexTuple. The attribute number is 1-based, i.e. the first columns attno is 1. Returns TRUE if supported, else FALSE. If the access method does not support index-only scans at all, the amcanreturn field in its pg_am row can be set to zero.

```c
void amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in Section 58.6, below.

```c
bytea *
amoptions (ArrayType *reloptions,
    bool validate);
```

Parse and validate the reloptions array for an index. This is called only when a non-null reloptions array exists for the index. reloptions is a text array containing entries of the form name=value. The function should construct a bytea value, which will be copied into the rd_options field of the index’s relcache entry. The data contents of the bytea value are open for the access method to define; most of the standard access methods use struct StdRdOptions. When validate is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when validate is false, invalid entries should be silently ignored. (validate is false when loading options already stored in pg_catalog; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return NULL if default behavior is wanted.

The purpose of an index, of course, is to support scans for tuples matching an indexable WHERE condition, often called a qualifier or scan key. The semantics of index scanning are described more fully in Section 58.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```c
IndexScanDesc ambeginscan (Relation indexRelation,
    int nkeys,
    int norderbys);
```
Prepare for an index scan. The nkeys and norderbys parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren’t provided yet. The result must be a palloc’d struct. For implementation reasons the index access method must create this struct by calling RelationGetIndexScan(). In most cases ambeginscan does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in amrescan.

```c
void
amrescan (IndexScanDesc scan,
           ScanKey keys,
           int nkeys,
           ScanKey orderbys,
           int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for keys and/or orderbys.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to ambeginscan. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.

```c
boolean
amgettuplex (IndexScanDesc scan,
             ScanDirection direction);
```

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the scan structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller’s snapshot test. On success, amgettuplex must also set scan->xs_recheck to TRUE or FALSE. FALSE means it is certain that the index entry matches the scan keys. TRUE means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by amgettuplex callers.

If the index supports index-only scans (i.e., amcanreturn returns TRUE for it), then on success the AM must also check scan->xs_want_itup, and if that is true it must return the original indexed data for the index entry, in the form of an IndexTuple pointer stored at scan->xs_itup, with tuple descriptor scan->xs_itupdesc. (Management of the data referenced by the pointer is the access method’s responsibility. The data must remain good at least until the next amgettuplex, amrescan, or amendscan call for the scan.)

The amgettuplex function need only be provided if the access method supports “plain” index scans. If it doesn’t, the amgettuplex field in its pg_am row must be set to zero.

```c
int64
amgetbitmap (IndexScanDesc scan,
              TIDBitmap *tbm);
```

Fetch all tuples in the given scan and add them to the caller-supplied TIDBitmap (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might
Chapter 58. Index Access Method Interface Definition

be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, `amgetbitmap` can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the `xs_recheck` output parameter of `amgettuple`. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. `amgetbitmap` and `amgettuple` cannot be used in the same index scan; there are other restrictions too when using `amgetbitmap`, as explained in Section 58.3.

The `amgetbitmap` function need only be provided if the access method supports “bitmap” index scans. If it doesn’t, the `amgetbitmap` field in its `pg_am` row must be set to zero.

```c
void amendscan (IndexScanDesc scan);
```

End a scan and release resources. The `scan` struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by `ambeginscan` and other scan-related functions.

```c
void ammarkpos (IndexScanDesc scan);
```

Mark current scan position. The access method need only support one remembered scan position per scan.

```c
void amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

By convention, the `pg_proc` entry for an index access method function should show the correct number of arguments, but declare them all as type `internal` (since most of the arguments have types that are not known to SQL, and we don’t want users calling the functions directly anyway). The return type is declared as `void`, `internal`, or `boolean` as appropriate. The only exception is `amoptions`, which should be correctly declared as taking `text[]` and `bool` and returning `bytea`. This provision allows client code to execute `amoptions` to test validity of options settings.

58.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the `scan keys`. The access method is not involved in actually fetching those tuples from the index’s parent table, nor in determining whether they pass the scan’s time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form `index_key operator constant`, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is `lossy`, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries
that do not. The core system’s index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the \texttt{WHERE} clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given \texttt{WHERE x > 4 AND x > 14} where \(x\) is a b-tree indexed column, it is left to the b-tree \texttt{amrescan} function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during \texttt{amrescan} will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set \texttt{pg_am.amcanorder} to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.

- Access methods that support ordering operators should set \texttt{pg_am.amcanorderbyop} to true. This indicates that the index is capable of returning entries in an order satisfying \texttt{ORDER BY index_key operator constant}. Scan modifiers of that form can be passed to \texttt{amrescan} as described previously.

The \texttt{amgettuple} function has a direction argument, which can be either \texttt{ForwardScanDirection} (the normal case) or \texttt{BackwardScanDirection}. If the first call after \texttt{amrescan} specifies \texttt{BackwardScanDirection}, then the set of matching index entries is to be scanned back-to-front rather than in the normal front-to-back direction, so \texttt{amgettuple} must return the last matching tuple in the index, rather than the first one as it normally would. (This will only occur for access methods that set \texttt{amcanorder} to true.) After the first call, \texttt{amgettuple} must be prepared to advance the scan in either direction from the most recently returned entry. (But if \texttt{pg_am.amcanbackward} is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later returning to the marked position. The same position might be restored multiple times. However, only one position need be remembered per scan; a new \texttt{ammarkpos} call overrides the previously marked position. An access method that does not support ordered scans should still provide mark and restore functions in \texttt{pg_am}, but it is sufficient to have them throw errors if called.

Both the scan position and the mark position (if any) must be maintained consistently in the face of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned by a scan that would have found the entry if it had existed when the scan started, or for the scan to return such an entry upon rescanning or backing up even though it had not been returned the first time through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is important is that insertions or deletions not cause the scan to miss or multiply return entries that were not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is useful to support index-only scans, in which the index returns the actual data not just the TID of the heap tuple. This will only work if the visibility map shows that the TID is on an all-visible page; else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the access method’s.
Instead of using `amgettuple`, an index scan can be done with `amgetbitmap` to fetch all tuples in one call. This can be noticeably more efficient than `amgettuple` because it allows avoiding lock/unlock cycles within the access method. In principle, `amgetbitmap` should have the same effects as repeated `amgettuple` calls, but we impose several restrictions to simplify matters. First of all, `amgetbitmap` returns all tuples at once and marking or restoring scan positions isn’t supported. Secondly, the tuples are returned in a bitmap which doesn’t have any specific ordering, which is why `amgetbitmap` doesn’t take a direction argument. (Ordering operators will never be supplied for such a scan, either.) Also, there is no provision for index-only scans with `amgetbitmap`, since there is no way to return the contents of index tuples. Finally, `amgetbitmap` does not guarantee any locking of the returned tuples, with implications spelled out in Section 58.4.

Note that it is permitted for an access method to implement only `amgetbitmap` and not `amgettuple`, or vice versa, if its internal implementation is unsuited to one API or the other.

### 58.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The core PostgreSQL system obtains `AccessShareLock` on the index during an index scan, and `RowExclusiveLock` when updating the index (including plain `VACUUM`). Since these lock types do not conflict, the access method is responsible for handling any fine-grained locking it might need. An exclusive lock on the index as a whole will be taken only during index creation, destruction, or `REINDEX`.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis of the required behavior. For the b-tree and hash index types, you can read about the design decisions involved in `src/backend/access/nbtree/README` and `src/backend/access/hash/README`.

Aside from the index’s own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the `heap`) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 58.5.)

- When a heap entry is to be deleted (by `VACUUM`), all its index entries must be removed first.

- An index scan must maintain a pin on the index page holding the item last returned by `amgettuple`, and `ambulkdelete` cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by `VACUUM`, and then to arrive at the corresponding heap entry after that was removed by `VACUUM`. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by `heap_fetch()`. But what if a third backend has already re-used the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as `SnapshotAny`), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index
Chapter 58. Index Access Method Interface Definition

Page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching
heap entry. Making ambulkdelete block on such a pin ensures that VACUUM cannot delete the heap entry
before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in
the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately af-
ter scanning the corresponding index entry. This is expensive for a number of reasons. An “asynchronous”
scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires
much less index locking overhead and can allow a more efficient heap access pattern. Per the above analy-
ysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous
scan is workable for a query using an MVCC snapshot.

In an amgetbitmap index scan, the access method does not keep an index pin on any of the returned
tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the ampredlocks flag is not set, any scan using that index access method within a serializable
transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write
conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain
patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of
those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index
access method implements finer-grained predicate locking, which will tend to reduce the frequency of
such transaction cancellations.

58.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using unique indexes, which are indexes that
disallow multiple entries with identical keys. An access method that supports this feature sets
pg_am.amcanunique true. (At present, only b-tree supports it.)

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the
entries might refer to successive versions of a single logical row. The behavior we actually want to enforce
is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the
following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since
  an UPDATE always deletes the old row version before inserting the new version, this will allow an
  UPDATE on a row without changing the key.)

- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must
  wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without
  deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other
  transaction to end and then redo the visibility check in toto.)

- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-
  be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access
method must recheck the liveness of the row being inserted. If it is committed dead then no violation
should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just
been created by the current transaction. It can happen during `CREATE UNIQUE INDEX CONCURRENTLY`, however.

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the `aminsert` function is passed a `checkUnique` parameter having one of the following values:

- `UNIQUE_CHECK_NO` indicates that no uniqueness checking should be done (this is not a unique index).
- `UNIQUE_CHECK_YES` indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.
- `UNIQUE_CHECK_PARTIAL` indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning `FALSE` from `aminsert`. For each row for which `FALSE` is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.

- `UNIQUE_CHECK_EXISTING` indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a `UNIQUE_CHECK_EXISTING` call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.
58.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calls to standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```c
void amcostestimate (PlannerInfo *root,
    IndexPath *path,
    double loop_count,
    Cost *indexStartupCost,
    Cost *indexTotalCost,
    Selectivity *indexSelectivity,
    double *indexCorrelation);
```

The first three parameters are inputs:

- `root`:
  The planner’s information about the query being processed.

- `path`:
  The index access path being considered. All fields except cost and selectivity values are valid.

- `loop_count`:
  The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger `loop_count` means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:

- `*indexStartupCost`:
  Set to cost of index start-up processing

- `*indexTotalCost`:
  Set to total cost of index processing

- `*indexSelectivity`:
  Set to index selectivity

- `*indexCorrelation`:
  Set to correlation coefficient between index scan order and underlying table’s order
Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by `src/backend/optimizer/path/costsize.c`: a sequential disk block fetch has cost `seq_page_cost`, a nonsequential fetch has cost `random_page_cost`, and the cost of processing one index row should usually be taken as `cpu_index_tuple_cost`. In addition, an appropriate multiple of `cpu_operator_cost` should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The `indexSelectivity` should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The `indexCorrelation` should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When `loop_count` is greater than one, the returned numbers should be averages expected for any one scan of the index.

**Cost Estimation**

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function `clauselist_selectivity()`:
   ```c
   *indexSelectivity = clauselist_selectivity(root, path->indexquals, 
      path->indexinfo->rel->relid, 
      JOIN_INNER, NULL);
   ```
2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as `indexSelectivity` times the number of rows in the index, but it might be more. (Note that the index’s size in pages and rows is available from the `path->indexinfo` struct.)
3. Estimate the number of index pages that will be retrieved during the scan. This might be just `indexSelectivity` times the index’s size in pages.
4. Compute the index access cost. A generic estimator might do this:
   ```c
   /*
   * Our generic assumption is that the index pages will be read
   * sequentially, so they cost seq_page_cost each, not random_page_cost.
   * Also, we charge for evaluation of the indexquals at each index row.
   * All the costs are assumed to be paid incrementally during the scan.
   */
   cost_qual_eval(&index_qual_cost, path->indexquals, root);
   ```
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
                 (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from
   pg_statistic. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in src/backend/utils/adt/selfuncs.c.
Chapter 59. GiST Indexes

59.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley’s GiST Indexing Project web site¹ and Marcel Kornacker’s thesis, Access Methods for Next-Generation Database Systems². The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site³.

59.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 59-1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

Table 59-1. Built-in GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;&lt;</td>
<td>&gt;&gt; &lt;&lt;</td>
</tr>
<tr>
<td>circle_ops</td>
<td>circle</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;&lt;</td>
<td>&gt;&gt; &lt;&lt;</td>
</tr>
<tr>
<td>inet_ops</td>
<td>inet, cidr</td>
<td>&amp;&amp; &gt;&gt;&gt; &gt;&gt;&gt;&gt;&gt; &gt; ==</td>
<td>&lt; &lt; &lt; &lt; &lt; = =</td>
</tr>
<tr>
<td>point_ops</td>
<td>point</td>
<td>&gt;&gt;&gt; ^ ^ ^ ^ ^ ^ ^</td>
<td>^ ^ ^ ^ ^ ^ ^</td>
</tr>
<tr>
<td>poly_ops</td>
<td>polygon</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt;&lt;</td>
<td>&gt;&gt; &lt;&lt;</td>
</tr>
</tbody>
</table>

¹. http://gist.cs.berkeley.edu/
Chapter 59. GiST Indexes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>$&lt;$ $&lt;=$ $&gt;$ $&lt;$ $&lt;=$</td>
<td>$&gt;$ $&lt;$ $&lt;=$</td>
</tr>
<tr>
<td>tsquery_ops</td>
<td>tsquery</td>
<td>$&lt;$ $&lt;=$ $&gt;$ $&lt;$ $&lt;=$</td>
<td>$&gt;$ $&lt;$ $&lt;=$</td>
</tr>
<tr>
<td>tsvector_ops</td>
<td>tsvector</td>
<td>$&lt;$ $&lt;=$ $&gt;$ $&lt;$ $&lt;=$</td>
<td>$&gt;$ $&lt;$ $&lt;=$</td>
</tr>
</tbody>
</table>

For historical reasons, the inet_ops operator class is not the default class for types inet and cidr. To use it, mention the class name in CREATE INDEX, for example

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 59.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates ($<$, $<=$, $>$), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and two that are optional. Correctness of the index is ensured by proper implementation of the same, consistent and union methods, while efficiency (size and speed) of the index will depend on the penalty and picksplit methods. The remaining two basic methods are compress and decompress, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about varlena for variable sized data). If the tree’s internal data type exists at the SQL level, the STORAGE option of the CREATE OPERATOR CLASS command can be used. The optional eighth method is distance, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method fetch is needed if the operator class wishes to support index-only scans.
consistent

Given an index entry \( p \) and a query value \( q \), this function determines whether the index entry is "consistent" with the query; that is, could the predicate "indexed_column indexable_operator \( q \)" be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is true, a recheck flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If \( \text{recheck} = \text{false} \) then the index has tested the predicate condition exactly, whereas if \( \text{recheck} = \text{true} \) the row is only a candidate match. In that case the system will automatically evaluate the indexable_operator against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal) RETURNS bool AS 'MODULE_PATHNAME' LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_consistent);
Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
bool *recheck = (bool *) PG_GETARG_POINTER(4);
data_type *key = DatumGetDataType(entry->key);
bool retval;

    /*
     * determine return value as a function of strategy, key and query.
     *
     * Use GIST_LEAF(entry) to know where you’re called in the index tree,
     * which comes handy when supporting the = operator for example (you could
     * check for non empty union() in non-leaf nodes and equality in leaf
     * nodes).
     */
    *recheck = true;    /* or false if check is exact */

    PG_RETURN_BOOL(retval);
}
```

Here, \( \text{key} \) is an element in the index and \( \text{query} \) the value being looked up in the index. The \( \text{StrategyNumber} \) parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the \text{CREATE OPERATOR CLASS} command. Depending on what operators you have included in the class, the data type of \( \text{query} \) could vary with the operator, but the above skeleton assumes it doesn’t.
This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
    *tmp,
    *old;
    int numranges,
        i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
    {
        out = data_type_deep_copy(tmp);

        PG_RETURN_DATA_TYPE_P(out);
    }

    for (i = 1; i < numranges; i++)
    {
        old = out;
        tmp = DatumGetDataType(ent[i].key);
        out = my_union_implementation(out, tmp);
    }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we’re dealing with a data type where \( \text{union}(X, Y, Z) = \text{union}(\text{union}(X, Y), Z) \). It’s easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The `union` implementation function should return a pointer to newly `palloc()`ed memory. You can’t just return whatever the input is.
Chapter 59. GiST Indexes

compress

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */
        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn’t do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt `compressed_data_type` to the specific type you’re converting to in order to compress your leaf nodes, of course.

decompress

The reverse of the `compress` method. Converts the index representation of the data item into a format that can be manipulated by the other GiST methods in the operator class.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_decompress(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_decompress);
```
Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}

The above skeleton is suitable for the case where no decompression is needed.

penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS ’MODULE_PATHNAME’
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
And the matching code in the C module could then follow this skeleton:
PG_FUNCTION_INFO_V1(my_penalty);

Datum
my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}

The penalty function is crucial to good performance of the index. It’ll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS ’MODULE_PATHNAME’
LANGUAGE C STRICT;
And the matching code in the C module could then follow this skeleton:
PG_FUNCTION_INFO_V1(my_picksplit);

Datum
my_picksplit(PG_FUNCTION_ARGS)
{
}
GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
OffsetNumber maxoff = entryvec->n - 1;
GISTENTRY *ent = entryvec->vector;
GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
int i,
nbytes;
OffsetNumber *left,
*right;
data_type *tmp_union;
data_type *unionL;
data_type *unionR;
GISTENTRY **raw_entryvec;

maxoff = entryvec->n - 1;
nbytes = (maxoff + 1) * sizeof(OffsetNumber);

v->spl_left = (OffsetNumber *) palloc(nbytes);
left = v->spl_left;
v->spl_nleft = 0;

v->spl_right = (OffsetNumber *) palloc(nbytes);
right = v->spl_right;
v->spl_nright = 0;

unionL = NULL;
unionR = NULL;

/* Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
  raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
{
  int real_index = raw_entryvec[i] - entryvec->vector;
  tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
  Assert(tmp_union != NULL);

  /*
   * Choose where to put the index entries and update unionL and unionR
   * accordingly. Append the entries to either v->spl_left or
   * v->spl_right, and care about the counters.
   */

  if (my_choice_is_left(unionL, curl, unionR, curr))
  {
    if (unionL == NULL)
      unionL = tmp_union;
    else
      unionL = my_union_implementation(unionL, tmp_union);

    *left = real_index;
  }
Like penalty, the picksplit function is crucial to good performance of the index. Designing suitable penalty and picksplit implementations is where the challenge of implementing well-performing GiST indexes lies.

**same**

Returns true if two index entries are identical, false otherwise.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
Datum
my_same(PG_FUNCTION_ARGS)
{
  prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
  prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
  bool *result = (bool *) PG_GETARG_POINTER(2);

  *result = my_eq(v1, v2);
  PG_RETURN_POINTER(result);
}
```

For historical reasons, the same function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument.

**distance**

Given an index entry \( p \) and a query value \( q \), this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.
The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_distance);

Datum
my_distance(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    data_type *query = PG_GETARG_DATA_TYPE_P(1);
    StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
    /* Oid subtype = PG_GETARG_OID(3); */
    /* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
    data_type *key = DatumGetDataType(entry->key);
    double retval;
    /*
     * determine return value as a function of strategy, key and query.
     */
    PG_RETURN_FLOAT8(retval);
}
```

The arguments to the distance function are identical to the arguments of the consistent function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry’s actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set *recheck to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns *recheck = true for any leaf node, the original ordering operator’s return type must be float8 or float4, and the distance function’s result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function’s result values can be any finite float8 values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that distance functions return these values.)

`fetch`

Converts the compressed index representation of the data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_fetch(internal)
RETURNS internal
AS 'MODULE_PATHNAME'
```
Chapter 59. GiST Indexes

LANGUAGE C STRICT;
The argument is a pointer to a GISTENTRY struct. On entry, its 'key' field contains a non-NULL leaf datum in its compressed form. The return value is another GISTENTRY struct, whose 'key' field contains the same datum in the original, uncompressed form. If the opclass' compress function does nothing for leaf entries, the fetch method can return the argument as is.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);

Datum
my_fetch(PG_FUNCTION_ARGS)
{
    GISTENTRY  *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    input_data_type *in = DatumGetPointer(entry->key);
    fetched_data_type *fetched_data;
    GISTENTRY  *retval;

    retval = palloc(sizeof(GISTENTRY));
    fetched_data = palloc(sizeof(fetched_data_type));

    /*
     * Convert 'fetched_data' into the a Datum of the original datatype.
     */
    /* fill *retval from fetched_data. */
    gistentryinit(*retval, PointerGetDatum(converted_datum),
                   entry->rel, entry->page, entry->offset, FALSE);

    PG_RETURN_POINTER(retval);
}
```

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a 'fetch' function.

All the GiST support methods are normally called in short-lived memory contexts; that is, CurrentMemoryContext will get reset after each tuple is processed. It is therefore not very important to worry about pfree’ing everything you palloc. However, in some cases it’s useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in fcinfo->flinfo->fn_mcxt, and keep a pointer to it in fcinfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

59.4. Implementation

59.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to
perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the penalty function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches effective_cache_size. It can be manually turned on or off by the buffering parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.

### 59.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for tsvector and tsquery) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see src/backend/access/gist/gistproc.c). The following contrib modules also contain GiST operator classes:

- **btree_gist**: B-tree equivalent functionality for several data types
- **cube**: Indexing for multidimensional cubes
- **hstore**: Module for storing (key, value) pairs
- **intarray**: RD-Tree for one-dimensional array of int4 values
- **ltree**: Indexing for tree-like structures
- **pg_trgm**: Text similarity using trigram matching
- **seg**: Indexing for “float ranges”
Chapter 60. SP-GiST Indexes

60.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University’s SP-GiST Indexing Project web site\(^1\). The SP-GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site\(^2\).

60.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 60-1.

Table 60-1. Built-in SP-GiST Operator Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>kd_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt; &lt; &gt; &gt; &gt; ^ ^=</td>
</tr>
<tr>
<td>quad_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt; &lt; &gt; &gt; &gt; ^ ^=</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&amp;&amp; &amp; &amp; &gt;</td>
</tr>
<tr>
<td>text_ops</td>
<td>text</td>
<td>&lt; &lt;= = &gt; = = &lt;= ~ &lt;= ~ &gt;= ~</td>
</tr>
</tbody>
</table>

Of the two operator classes for type point, quad_point_ops is the default. kd_point_ops supports the same operators but uses a different index data structure that may offer better performance in some

---

60.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more nodes, which represent groups of similar leaf values. A node contains a downlink that leads to either another, lower-level inner tuple, or a short list of leaf tuples that all lie on the same index page. Each node has a label that describes it; for example, in a radix tree the node label could be the next character of the string value. Optionally, an inner tuple can have a prefix value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed.

Note: The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two internal arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return void, since all their results appear in the output struct; but leaf_consistent additionally returns a boolean result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.
The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_config(internal, internal) RETURNS void ... 
```

The first argument is a pointer to a `spgConfigIn` C struct, containing input data for the function. The second argument is a pointer to a `spgConfigOut` C struct, which the function must fill with result data.

```c
typedef struct spgConfigIn
{
    Oid attType; /* Data type to be indexed */
} spgConfigIn;
```

```c
typedef struct spgConfigOut
{
    Oid prefixType; /* Data type of inner-tuple prefixes */
    Oid labelType; /* Data type of inner-tuple node labels */
    bool canReturnData; /* Opclass can reconstruct original data */
    bool longValuesOK; /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

`attType` is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, `prefixType` can be set to `VOIDOID`. Likewise, for operator classes that do not use node labels, `labelType` can be set to `VOIDOID`. `canReturnData` should be set true if the operator class is capable of reconstructing the originally-supplied index value. `longValuesOK` should be set true only when the `attType` is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 60.4.1).

`choose`

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_choose(internal, internal) RETURNS void ... 
```

The first argument is a pointer to a `spgChooseIn` C struct, containing input data for the function. The second argument is a pointer to a `spgChooseOut` C struct, which the function must fill with result data.

```c
typedef struct spgChooseIn
{
    Datum datum; /* original datum to be indexed */
    Datum leafDatum; /* current datum to be stored at leaf */
    int level; /* current level (counting from zero) */

    /* Data from current inner tuple */
    bool allTheSame; /* tuple is marked all-the-same? */
    bool hasPrefix; /* tuple has a prefix? */
    Datum prefixDatum; /* if so, the prefix value */
    int nNodes; /* number of nodes in the inner tuple */
    Datum *nodeLabels; /* node label values (NULL if none) */
} spgChooseIn;
```

```c
typedef enum spgChooseResultType
{
    spgMatchNode = 1, /* descend into existing node */
```
Chapter 60. SP-GiST Indexes

spgAddNode, /**< add a node to the inner tuple */
spgSplitTuple /**< split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
{
    spgChooseResultType resultType; /**< action code, see above */
    union
    {
        struct /**< results for spgMatchNode */
        {
            int nodeN; /**< descend to this node (index from 0) */
            int levelAdd; /**< increment level by this much */
            Datum restDatum; /**< new leaf datum */
        } matchNode;
        struct /**< results for spgAddNode */
        {
            Datum nodeLabel; /**< new node’s label */
            int nodeN; /**< where to insert it (index from 0) */
        } addNode;
        struct /**< results for spgSplitTuple */
        {
            /* Info to form new inner tuple with one node */
            bool prefixHasPrefix; /**< tuple should have a prefix? */
            Datum prefixPrefixDatum; /**< if so, its value */
            Datum nodeLabel; /**< node’s label */
        } splitNode;
        /* Info to form new lower-level inner tuple with all old nodes */
        bool postfixHasPrefix; /**< tuple should have a prefix? */
        Datum postfixPrefixDatum; /**< if so, its value */
    } result;
} spgChooseOut;

datum is the original datum that was to be inserted into the index. leafDatum is initially the same as datum, but can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple’s level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 60.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal datum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.
If a new child node must be added, set `resultType` to `spgAddNode`. Set `nodeLabel` to the label to be used for the new node, and set `nodeN` to the index (from zero) at which to insert the node in the node array. After the node has been added, the `choose` function will be called again with the modified inner tuple; that call should result in an `spgMatchNode` result.

If the new value is inconsistent with the tuple prefix, set `resultType` to `spgSplitTuple`. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set `prefixHasPrefix` to indicate whether the new upper tuple should have a prefix, and if so set `prefixPrefixDatum` to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed, and it should be no longer than the original prefix. Set `nodeLabel` to the label to be used for the node that will point to the new lower-level inner tuple. Set `postfixHasPrefix` to indicate whether the new lower-level inner tuple should have a prefix, and if so set `postfixPrefixDatum` to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the `choose` function will be called again with the replacement inner tuple. That call will usually result in an `spgAddNode` result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns `spgMatchNode` and allows the insertion to descend to the leaf level.

**picksplit**

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...}
```

The first argument is a pointer to a `spgPickSplitIn` C struct, containing input data for the function. The second argument is a pointer to a `spgPickSplitOut` C struct, which the function must fill with result data.

```c
typedef struct spgPickSplitIn {
    int nTuples; /* number of leaf tuples */
    Datum *datums; /* their datums (array of length nTuples) */
    int level; /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut {
    bool hasPrefix; /* new inner tuple should have a prefix? */
    Datum prefixDatum; /* if so, its value */
    int nNodes; /* number of nodes for new inner tuple */
    Datum *nodeLabels; /* their labels (or NULL for no labels) */

    int *mapTuplesToNodes; /* node index for each leaf tuple */
    Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;
```

`nTuples` is the number of leaf tuples provided. `datums` is an array of their datum values. `level` is the current level that all the leaf tuples share, which will become the level of the new inner tuple.
Set `hasPrefix` to indicate whether the new inner tuple should have a prefix, and if so set `prefixDatum` to the prefix value. Set `nNodes` to indicate the number of nodes that the new inner tuple will contain, and set `nodeLabels` to an array of their label values. (If the nodes do not require labels, set `nodeLabels` to NULL; see Section 60.4.2 for details.) Set `mapTuplesToNodes` to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set `leafTupleDatums` to an array of the values to be stored in the new leaf tuples (these will be the same as the input `datums` if the operator class does not modify datums from one level to the next). Note that the `picksplit` function is responsible for `palloc`ing the `nodeLabels`, `mapTuplesToNodes` and `leafTupleDatums` arrays.

If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See Section 60.4.3 for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 60.4.1 for more information.

`inner_consistent`

Returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn C struct`, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut C struct`, which the function must fill with result data.

```c
typedef struct spgInnerConsistentIn
{
    ScanKey  scankeys;     /* array of operators and comparison values */
    int      nkeys;        /* length of array */
    Datum    reconstructedValue;   /* value reconstructed at parent */
    int      level;        /* current level (counting from zero) */
    bool     returnData;   /* original data must be returned? */
    bool     allTheSame;   /* tuple is marked all-the-same? */
    bool     hasPrefix;    /* tuple has a prefix? */
    Datum    prefixDatum;  /* if so, the prefix value */
    int      nNodes;       /* number of nodes in the inner tuple */
    Datum    *nodeLabels;  /* node label values (NULL if none) */
} spgInnerConsistentIn;
```

```c
typedef struct spgInnerConsistentOut
```
The array \texttt{scankeys}, of length \texttt{nkeys}, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that \texttt{nkeys = 0} implies that all index entries satisfy the query.) Usually the consistent function only cares about the \texttt{sk\_strategy} and \texttt{sk\_argument} fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check \texttt{sk\_flags} to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. \texttt{reconstructedValue} is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the \texttt{inner\_consistent} function did not provide a value at the parent level. \texttt{level} is the current inner tuple’s level, starting at zero for the root level. \texttt{returnData} is \texttt{true} if reconstructed data is required for this query; this will only be so if the \texttt{config} function asserted \texttt{can\_return\_data}. \texttt{allTheSame} is \texttt{true} if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 60.4.3). \texttt{has\_prefix} is \texttt{true} if the current inner tuple contains a prefix; if so, \texttt{prefix\_Datum} is its value. \texttt{nNodes} is the number of child nodes contained in the inner tuple, and \texttt{node\_Labels} is an array of their label values, or NULL if the nodes do not have labels.

\texttt{nNodes} must be set to the number of child nodes that need to be visited by the search, and \texttt{node\_Numbers} must be set to an array of their indexes. If the operator class keeps track of levels, set \texttt{level\_Adds} to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that’s not necessarily so, so an array is used.) If value reconstruction is needed, set \texttt{reconstructed\_Values} to an array of the values reconstructed for each child node to be visited; otherwise, leave \texttt{reconstructed\_Values} as NULL. Note that the \texttt{inner\_consistent} function is responsible for \texttt{palloc’ing} the \texttt{node\_Numbers}, \texttt{level\_Adds} and \texttt{reconstructed\_Values} arrays.

\texttt{leaf\_consistent}

Returns \texttt{true} if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

\texttt{CREATE FUNCTION my\_leaf\_consistent(internal, internal) RETURNS bool ...}

The first argument is a pointer to a \texttt{spg\_Leaf\_Consistent\_In} C struct, containing input data for the function. The second argument is a pointer to a \texttt{spg\_Leaf\_Consistent\_Out} C struct, which the function must fill with result data.

\texttt{typedef struct spg\_Leaf\_Consistent\_In}

\{
    ScanKey scankeys;    /* array of operators and comparison values */
    int nkeys;           /* length of array */
    Datum reconstructedValue;  /* value reconstructed at parent */
    int level;           /* current level (counting from zero) */
    bool returnData;     /* original data must be returned? */
    Datum leafDatum;     /* datum in leaf tuple */
\} spg\_Leaf\_Consistent\_In;
The array `scankeys` of length `nkeys` describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check `sk_flags` to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions.

`reconstructedValue` is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the `inner_consistent` function did not provide a value at the parent level. `level` is the current leaf tuple’s level, starting at zero for the root level. `returnData` is true if reconstructed data is required for this query; this will only be so if the `config` function asserted `canReturnData`. `leafDatum` is the key value stored in the current leaf tuple.

The function must return `true` if the leaf tuple matches the query, or `false` if not. In the `true` case, if `returnData` is `true` then `leafValue` must be set to the value originally supplied to be indexed for this leaf tuple. Also, `recheck` may be set to `true` if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, `CurrentMemoryContext` will be reset after processing of each tuple. It is therefore not very important to worry about `pfree’ing everything you `palloc`. (The `config` method is an exception: it should try to avoid leaking memory. But usually the `config` method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard `PG_GET_COLLATION()` mechanism.

### 60.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

#### 60.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8KB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set `longValuesOK` to `TRUE` only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.
Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide the set of leaf values into more than one node group. If the operator class’s \texttt{picksplit} function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 60.4.3.

### 60.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the \texttt{picksplit} function can return \texttt{NULL} for the \texttt{nodeLabels} array. This will in turn result in \texttt{nodeLabels} being \texttt{NULL} during subsequent calls to \texttt{choose} and \texttt{inner_consistent}. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for \texttt{choose} to return \texttt{spgAddNode}, since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in \texttt{spgSplitTuple} actions, since it is expected that an \texttt{spgAddNode} action will be needed as well.

### 60.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class’s \texttt{picksplit} function when \texttt{picksplit} fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that \texttt{picksplit} gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The \texttt{allTheSame} flag is set on the inner tuple to warn the \texttt{choose} and \texttt{inner_consistent} functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an \texttt{allTheSame} tuple, a \texttt{choose} result of \texttt{spgMatchNode} is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied \texttt{nodeN} value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for \texttt{choose} to return \texttt{spgAddNode}, since that would make the nodes not all equivalent; the \texttt{spgSplitTuple} action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an \texttt{allTheSame} tuple, the \texttt{inner_consistent} function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the \texttt{inner_consistent} function normally assumes about the meaning of the nodes.

### 60.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST.
core system currently provides radix trees over text columns and two types of trees over points: quad-tree and k-d tree. Look into `src/backend/access/spgist/` to see the code.
Chapter 61. GIN Indexes

61.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be indexed are composite values, and the queries to be handled by the index need to search for element values that appear within the composite items. For example, the items could be documents, and the queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more than one key. Each key value is stored only once, so a GIN index is very compact for cases where the same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the specific operations that it accelerates. Instead, it uses custom strategies defined for particular data types. The strategy defines how keys are extracted from indexed items and query conditions, and how to determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert. This is much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov. There is more information about GIN on their website.

61.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 61-1. (Some of the optional modules described in Appendix F provide additional GIN operator classes.)

</tr>
</tbody>
</table>

Of the two operator classes for type `jsonb`, `jsonb_ops` is the default. `jsonb_path_ops` supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

### 61.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define
the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null keys are never passed to this function.

```c
Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)
```

Returns a palloc’d array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

```c
Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool **pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)
```

Returns a palloc’d array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 35.14.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

**searchMode** is an output argument that allows extractQuery to specify details about how the search will be done. If *searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If *searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If *searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.

**pmatch** is an output argument for use when partial match is supported. To use it, extractQuery must allocate an array of *nkeys booleans and store its address at *pmatch. Each element of the array should be set to TRUE if the corresponding key requires partial match, FALSE if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.

**extra_data** is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be
ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.

```c
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])
```

Returns TRUE if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item's value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is TRUE if the indexed item contains the corresponding query key, i.e., if (check[i] == TRUE) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is TRUE if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to TRUE if the heap tuple needs to be rechecked against the query operator, or FALSE if the index test is exact. That is, a FALSE return value guarantees that the heap tuple does not match the query; a TRUE return value with *recheck set to FALSE guarantees that the heap tuple does match the query; and a TRUE return value with *recheck set to TRUE means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

```c
GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])
```

triConsistent is similar to consistent, but instead of a boolean check[], there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular boolean values. GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e. the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, GIN_MAYBE return value is equivalent of setting recheck flag in the boolean consistent function.

Optionally, an operator class for GIN can supply the following method:
Chapter 61. GIN Indexes

int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number \( n \) of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, \( \text{extra\_data} \) is the corresponding element of the extra-data array made by extractQuery, or NULL if none. Null keys are never passed to this function.

To support “partial match” queries, an operator class must provide the \( \text{comparePartial} \) method, and its extractQuery method must set the \( \text{pmatch} \) parameter when a partial-match query is encountered. See Section 61.4.2 for details.

The actual data types of the various Datum values mentioned above vary depending on the operator class. The item values passed to extractValue are always of the operator class’s input type, and all key values must be of the class’s STORAGE type. The type of the \( \text{query} \) argument passed to extractQuery, consistent and triConsistent is whatever is specified as the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the item type, so long as key values of the correct type can be extracted from it.

61.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

61.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed, or if the pending list becomes larger than gin_pending_list_limit, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.
Chapter 61. GIN Indexes

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the `fastupdate` storage parameter for a GIN index. See CREATE INDEX for details.

61.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the `compare` support method). The `extractQuery` method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the `pmatch` flag true. The key range is then scanned using the `comparePartial` method. `comparePartial` must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

61.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 61.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

`maintenance_work_mem`

Build time for a GIN index is very sensitive to the `maintenance_work_mem` setting; it doesn’t pay to skimp on work memory during index creation.

`gin_pending_list_limit`

During a series of insertions into an existing GIN index that has `fastupdate` enabled, the system will clean up the pending-entry list whenever the list grows larger than `gin_pending_list_limit`. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing `gin_pending_list_limit` or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

`gin_pending_list_limit` can be overridden for individual GIN indexes by changing storage parameters, and which allows each GIN index to have its own cleanup threshold. For example, it’s
possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

**gin_fuzzy_search_limit**

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the `gin_fuzzy_search_limit` configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.

“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator.

From experience, values in the thousands (e.g., 5000 — 20000) work well.

### 61.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

### 61.7. Examples

The PostgreSQL source distribution includes GIN operator classes for `tsvector` and for one-dimensional arrays of all internal types. Prefix searching in `tsvector` is implemented using the GIN partial match feature. The following `contrib` modules also contain GIN operator classes:

- **btree_gin**
  - B-tree equivalent functionality for several data types

- **hstore**
  - Module for storing (key, value) pairs

- **intarray**
  - Enhanced support for `int[]`

- **pg_trgm**
  - Text similarity using trigram matching
Chapter 62. BRIN Indexes

62.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store's sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the `pages_per_range` storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for `pages_per_range`. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

62.1.1. Index Maintenance

At the time of creation, all existing index pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the `brin_summarize_new_values(regclass)` function, or automatically when VACUUM processes the table.
### 62.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 62-1.

The `minmax` operator classes store the minimum and the maximum values appearing in the indexed column within the range. The `inclusion` operator classes store a value which includes the values in the indexed column within the range.

### 62.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

- `BrinOpcInfo *opcInfo(Oid type_oid)`
  
  Returns internal information about the indexed columns’ summary data. The return value must point to a `palloc`d `BrinOpcInfo`, which has this definition:

  ```c
  typedef struct BrinOpcInfo
  {
  /* Number of columns stored in an index column of this opclass */
  uint16   oi_nstored;
  /* Opaque pointer for the opclass’ private use */
  void    *oiOpaque;
  /* Type cache entries of the stored columns */
  TypeCacheEntry *oi_typcache[FLEXIBLE_ARRAY_MEMBER];
  } BrinOpcInfo;
  ```

  `BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support procedures during an index scan.

- `bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)`
  
  Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

- `bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)`
  
  Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

- `bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)`
  
  Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

The core distribution includes support for two types of operator classes: minmax and inclusion. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>timetz_minmax_ops</td>
<td>time with time zone</td>
<td>&lt;= &gt;=</td>
</tr>
<tr>
<td>uuid_minmax_ops</td>
<td>uuid</td>
<td>&lt;= &gt;=</td>
</tr>
</tbody>
</table>
write any source code; appropriate catalog entries being declared is enough. Note that assumptions about
the semantics of operator strategies are embedded in the support procedures’ source code.

Operator classes that implement completely different semantics are also possible, provided implementa-
tions of the four main support procedures described above are written. Note that backwards compatibility
across major releases is not guaranteed: for example, additional support procedures might be required in
later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the
minmax support procedures alongside the corresponding operators, as shown in Table 62-2. All operator
class members (procedures and operators) are mandatory.

Table 62-2. Procedure and Support Numbers for Minmax Operator Classes

<table>
<thead>
<tr>

</tr>
<tr>
<td>Operator Strategy 4</td>
<td>operator greater-than-or-equal-to</td>
</tr>
<tr>
<td>Operator Strategy 5</td>
<td>operator greater-than</td>
</tr>
</tbody>
</table>

To write an operator class for a complex datatype which has values included within another type, it’s
possible to use the inclusion support procedures alongside the corresponding operators, as shown in Table
62-3. It requires only a single additional function, which can be written in any language. More func-
tions can be defined for additional functionality. All operators are optional. Some operators require other
operators, as shown as dependencies on the table.

</tbody>
</table>

Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same datatype as the opclass, and return the union of them. The inclusion opclass can store union values with different datatypes if it is defined with the STORAGE parameter. The return value of the union function should match the STORAGE datatype.

Support procedure numbers 12 and 14 are provided to support irregularities of built-in datatypes. Procedure number 12 is used to support network addresses from different families which are not mergeable. Procedure number 14 is used to support empty ranges. Procedure number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion opclasses support cross-datatype operators, though with these the dependencies become more complicated. The minmax opclass requires a full set of operators to be defined with
both arguments having the same datatype. It allows additional datatypes to be supported by defining extra sets of operators. Inclusion opclass operator strategies are dependent on another operator strategy as shown in Table 62-3, or the same operator strategy as themselves. They require the dependency operator to be defined with the STORAGE datatype as the left-hand-side argument and the other supported datatype to be the right-hand-side argument of the supported operator. See float4_minmax_ops as an example of minmax, and box_inclusion_ops as an example of inclusion.
Chapter 63. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

63.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as PGDATA (after the name of the environment variable that can be used to define it). A common location for PGDATA is /var/lib/pgsql/data. Multiple clusters, managed by different server instances, can exist on the same machine.

The PGDATA directory contains several subdirectories and control files, as shown in Table 63-1. In addition to these required items, the cluster configuration files postgresql.conf, pg_hba.conf, and pg_ident.conf are traditionally stored in PGDATA, although it is possible to place them elsewhere.

Table 63-1. Contents of PGDATA

<table>

</tr>
</tbody>
</table>

For each database in the cluster there is a subdirectory within `PGDATA/base`, named after the database’s OID in `pg_database`. This subdirectory is the default location for the database’s files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index’s `filenode` number, which can be found in `pg_class.relfilenode`. But for temporary relations, the file name is of the form `tBBB_FFF`, where `BBB` is the backend ID of the backend which created the file, and `FFF` is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 63.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix `_fsm`. Tables also have a visibility map, stored in a fork with the suffix `_vm`, to track which pages are known to have no dead tuples. The visibility map is described further in Section 63.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix `_init` (see Section 63.5).
Caution

Note that while a table's filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment’s file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2, etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 63.2 for more information.

The contents of tables and indexes are discussed further in Section 63.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's CREATE TABLESPACE command). This symbolic link is named after the tablespace’s OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_20100805. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database’s OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablespace other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

63.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).
Chapter 63. Database Physical Storage

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type’s representation. The special representations collectively called TOASTed values work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it’s been detoasted. (This is normally done by invoking PG_DETOAST_DATUM before doing anything with an input value, but in some cases more efficient approaches are possible. See Section 35.11.1 for more detail.)

TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30} - 1$ bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren’t aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a TOAST pointer are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a TOAST table that is separate from, but associated with, the table containing the TOAST pointer datum itself. These on-disk pointer datums are created by the TOAST management code (in access/heap/tuptoaster.c) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 63.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 63.2.2.

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques. See src/common/pg_lzcompress.c for the details.
63.2.1. Out-of-line, on-disk TOAST storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s pg_class.reltoastrelid entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most TOAST_MAX_CHUNK_SIZE bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns chunk_id (an OID identifying the particular TOASTed value), chunk_seq (a sequence number for the chunk within its value), and chunk_data (the actual data of the chunk). A unique index on chunk_id and chunk_seq provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its chunk_id). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than TOAST_TUPLE_THRESHOLD bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than TOAST_TUPLE_TARGET bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- **EXTERNAL** allows out-of-line storage but not compression. Use of EXTERNAL will make substring operations on wide text and bytea columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with ALTER TABLE SET STORAGE.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sorts sets shrink also, and sorts will more often be done entirely.
in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

63.2.2. Out-of-line, in-memory TOAST storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to indirect data and pointers to expanded data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the $N$’th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it’s much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in \texttt{src/include/utils/expandeddatum.h}. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply \texttt{PG\_DETOAST\_DATUM} to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into read-write and read-only pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to make a modified version of the value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.
### 63.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of
available space in the relation. It’s stored alongside the main relation data in a separate relation fork,
named after the filenode number of the relation, plus a \_fsm suffix. For example, if the filenode of a
relation is 12345, the FSM is stored in a file called 12345_fsm, in the same directory as the main relation
file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free
space available on each heap (or index) page, using one byte to represent each such page. The upper
levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents
a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children’s values is stored.
The maximum value in the leaf nodes is therefore stored at the root.

See src/backend/storage/freespace/README for more details on how the FSM is structured, and
how it’s updated and searched. The pg_freespacemap module can be used to examine the information
stored in free space maps.

### 63.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are
known to be visible to all active transactions. It’s stored alongside the main relation data in a separate
relation fork, named after the filenode number of the relation, plus a \_vm suffix. For example, if the
filenode of a relation is 12345, the VM is stored in a file called 12345_vm, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map simply stores one bit per heap page. A set bit means that all tuples on the page are
known to be visible to all transactions. This means that the page does not contain any tuples that need
to be vacuumed. This information can also be used by index-only scans to answer queries using only the
index tuple.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition
is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but
are cleared by any data-modifying operations on a page.

### 63.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization
fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty
due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will
be recreated automatically as needed).
63.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 63-2 shows the overall layout of a page. There are five parts to each page.

Table 63-2. Overall Page Layout

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
<tr>
<td>ItemIdData</td>
<td>Array of item identifiers pointing to the actual items. Each entry is an (offset,length) pair. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item identifiers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 63-3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn’t follow the item layout rules.
Table 63-3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>
<td>PageXLogRecPtr</td>
<td>8 bytes</td>
<td>LSN: next byte after last byte of xlog record for last change to this page</td>
</tr>
<tr>

<td>Flag bits</td>
</tr>
<tr>
<td>pd_lower</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of free space</td>
</tr>
<tr>
<td>pd_upper</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to end of free space</td>
</tr>
<tr>
<td>pd_special</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of special space</td>
</tr>
<tr>
<td>pd_pagesize_version</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page size and layout version number information</td>
</tr>
<tr>
<td>pd_prune_xid</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at pd_lower, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting pd_special to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 63-4. The actual user data (columns of the row) begins at the offset indicated by t_hoff, which must always be a multiple of the MAXALIGN distance for the platform. The null bitmap is only present if the HEAP_HASNULL bit is set in t_infomask. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, t_natts bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the HEAP_HASOID bit is set in t_infomask.
present, it appears just before the $t_{\text{hoff}}$ boundary. Any padding needed to make $t_{\text{hoff}}$ a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 63-4. HeapTupleHeaderData Layout

<table>
<thead>

<td>offset to user data</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/access/htup_details.h.

Interpreting the actual data can only be done with information obtained from other tables, mostly pg_attribute. The key values needed to identify field locations are attlen and attalign. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null values. All this trickery is wrapped up in the functions heap_getattr, fastgetattr and heap_getsysattr.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it’s a variable length field (attlen = -1) then it’s a bit more complicated. All variable-length data types share the common header structure struct varlena, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 63.2).
Chapter 64. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named `genbki.pl`, which reads some specially formatted C header files in the `src/include/catalog/` directory of the source tree. The created BKI file is called `postgres.bki` and is normally installed in the `share` subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

### 64.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the `postgres.bki` file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with `#` are ignored.

### 64.2. BKI Commands

```
cREATE TABLE tablename (name1 = type1 [FORCE NOT NULL | FORCE NULL ], name2 = type2 [FORCE NOT NULL | FORCE NULL ], ...)
```

Create a table named `tablename`, and having the OID `tableoid`, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: `bool`, `bytea`, `char (1 byte)`, `name`, `int2`, `int4`, `regproc`, `regclass`, `regtype`, `text`, `oid`, `tid`, `xid`, `cid`, `int2vector`, `oidvector`, `_int4 (array)`, `_text (array)`, `_oid (array)`, `_char (array)`, `_aclitem (array)`. Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only

2245
these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When bootstrap is specified, the table will only be created on disk; nothing is entered into pg_class, pg_attribute, etc, for it. Thus the table will not be accessible by ordinary SQL operations until such entries are made the hard way (with insert commands). This option is used for creating pg_class etc themselves.

The table is created as shared if shared_relation is specified. It will have OIDs unless without_oids is specified. The table’s row type OID (pg_type OID) can optionally be specified via the rowtype_oid clause; if not specified, an OID is automatically generated for it. (The rowtype_oid clause is useless if bootstrap is specified, but it can be provided anyway for documentation.)

open tablename

Open the table named tablename for insertion of data. Any currently open table is closed.

close [tablename]

Close the open table. The name of the table can be given as a cross-check, but this is not required.

insert [OID = oid_value] ( value1 value2 ... )

Insert a new row into the open table using value1, value2, etc., for its column values and oid_value for its OID. If oid_value is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word _null_. Values containing spaces must be double quoted.

declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [, ...] )

Create an index named indexname, having OID indexoid, on the table named tablename, using the amname access method. The fields to index are called name1, name2 etc., and the operator classes to use are opclass1, opclass2 etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

declare toast toasttableoid toastindexoid on tablename

Create a TOAST table for the table named tablename. The TOAST table is assigned OID toasttableoid and its index is assigned OID toastindexoid. As with declare index, filling of the index is postponed.

build indices

Fill in the indices that have previously been declared.

64.3. Structure of the Bootstrap BKI File

The open command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are pg_class, pg_attribute, pg_proc, and pg_type.) To allow those tables themselves to be filled, create with the bootstrap option implicitly opens the created table for data insertion.
Chapter 64. BKI Backend Interface

Also, the declare index and declare toast commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the postgres.bki file has to be:

1. create bootstrap one of the critical tables
2. insert data describing at least the critical tables
3. close
4. Repeat for the other critical tables.
5. create (without bootstrap) a noncritical table
6. open
7. insert desired data
8. close
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. build indices

There are doubtless other, undocumented ordering dependencies.

### 64.4. Example

The following sequence of commands will create the table test_table with OID 420, having two columns cola and colb of type int4 and text, respectively, and insert two rows into the table:

```sql
create test_table 420 (cola = int4, colb = text)  
open test_table  
insert OID=421 ( 1 "value1" )  
insert OID=422 ( 2 _null_ )  
close test_table
```
Chapter 65. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

65.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since ANALYZE uses random sampling while producing statistics, the results will change slightly after any new ANALYZE.

Let’s start with a very simple query:

```
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of tenk1 is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in pg_class:

```
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples
----------+-----------
358 | 10000
```

These numbers are current as of the last VACUUM or ANALYZE on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from relpages then reltuples is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of relpages is up-to-date so the rows estimate is the same as reltuples.

Let’s move on to an example with a range condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
--------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (unique1 < 1000)
```

2248
Chapter 65. How the Planner Uses Statistics

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltssel. The scalarltssel function retrieves the histogram for uniquel from pg_statistics. For manual queries it is more convenient to look in the simpler pg_stats view:

SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='unique1';

<table>
<thead>
<tr>
<th>histogram_bounds</th>
</tr>
</thead>
<tbody>
<tr>
<td>{0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995}</td>
</tr>
</tbody>
</table>

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

\[
\text{selectivity} = \frac{1 + (1000 - \text{bucket}[2].\text{min})/(\text{bucket}[2].\text{max} - \text{bucket}[2].\text{min})}{\text{num_buckets}}
\]

\[
= \frac{1 + (1000 - 993)/(1997 - 993)}{10}
\]

\[
= 0.100697
\]

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

\[
\text{rows} = \text{rel_cardinality} \times \text{selectivity}
\]

\[
= 10000 \times 0.100697
\]

\[
= 1007 \text{ (rounding off)}
\]

Next let’s consider an example with an equality condition in its WHERE clause:

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = ‘CRAAAA’;

QUERY PLAN

-----------------------------------------------
| Seq Scan on tenk1 (cost=0.00..483.00 rows=30 width=244) |
| Filter: (stringu1 = ‘CRAAAA’::name) |

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

null_frac       | 0
Chapter 65. How the Planner Uses Statistics

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

\[
\text{selectivity} = \text{mcf}[3] = 0.003
\]

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

\[
\text{rows} = 10000 \times 0.003 = 30
\]

Now consider the same query, but with a constant that is not in the MCV list:

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)
Filter: (stringu1 = 'xxx'::name)
```

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

\[
\text{selectivity} = \frac{1 - \sum \text{mfv}}{\text{num_distinct} - \text{num_mcv}}
\]

\[
= \frac{1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003)}{676 - 10}
\]

\[
= 0.0014559
\]

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

\[
\text{rows} = 10000 \times 0.0014559 = 15 \text{ (rounding off)}
\]

The previous example with \( \text{unique1} < 1000 \) was an oversimplification of what \text{scalarltsel} really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since \text{unique1} is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation \text{scalarltsel} directly applies the condition (e.g., “\(< 1000\)”) to each value of the MCV list, and adds up
the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';
```

```
QUERY PLAN
```
```
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
  Filter: (stringu1 < 'IAAAAA':::name)
```

We already saw the MCV information for `stringu1`, and here is its histogram:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
histogram_bounds
--------------------------------------------------------------------------------
{AAAAAA,CQAAAA,FRAAAA,IBAAAA,KRAAAA,NFAAAA,PSAAAA,SGAAAA,VAAAAA,XLAAAA,ZZAAAA}
```

Checking the MCV list, we find that the condition `stringu1 < 'IAAAAA'` is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

```
selectivity = sum(relevant mvfs)
= 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
= 0.01833333
```

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value `IAAAAA` falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than `IAAAAA`. We then combine the estimates for the MCV and non-MCV populations:

```
selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
= 0.01833333 + 0.298387 * 0.96966667
= 0.307669
```

```
rows = 10000 * 0.307669
= 3077 (rounding off)
```

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the `WHERE` clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE uniquel < 1000 AND stringu1 = 'xxx';
```

```
QUERY PLAN
```
Chapter 65. How the Planner Uses Statistics

Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx'::name)
  -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

\[
selectivity = \text{selectivity(unique1 } < 1000) \times \text{selectivity(stringu1 } = \text{’xxx’)}
\]

\[
= 0.100697 \times 0.0014559 = 0.0001466
\]

\[
rows = 10000 \times 0.0001466 = 1 \text{ (rounding off)}
\]

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nested Loop (cost=4.64..456.23 rows=50 width=488)</td>
</tr>
<tr>
<td>-&gt; Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)</td>
</tr>
<tr>
<td>Recheck Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)</td>
</tr>
<tr>
<td>Index Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)</td>
</tr>
<tr>
<td>Index Cond: (unique2 = t1.unique2)</td>
</tr>
</tbody>
</table>

The restriction on tenk1.unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

\[
selectivity = \left(0 + \frac{(50 - \text{bucket[1].min})}{(\text{bucket[1].max} - \text{bucket[1].min})}\right)/\text{num_buckets}
\]

\[
= \left(0 + \frac{(50 - 0)}{(993 - 0)}\right)/10
\]

\[
= 0.005035
\]

\[
rows = 10000 \times 0.005035 = 50 \text{ (rounding off)}
\]

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:

SELECT tablename, null_frac,n_distinct, most_common_vals FROM pg_stats
WHERE tablename IN (‘tenk1’, ‘tenk2’) AND attname=’unique2’;
### Chapter 65. How the Planner Uses Statistics

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for `unique2` because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

\[
\text{selectivity} = (1 - \text{null_frac}_1) \times (1 - \text{null_frac}_2) \times \min(1/\text{num_distinct}_1, 1/\text{num_distinct}_2)
\]

\[
= (1 - 0) \times (1 - 0) / \max(10000, 10000)
\]

\[
= 0.0001
\]

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:

\[
\text{rows} = (\text{outer_cardinality} \times \text{inner_cardinality}) \times \text{selectivity}
\]

\[
= (50 \times 10000) \times 0.0001
\]

\[
= 50
\]

Had there been MCV lists for the two columns, `eqjoinsel` would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed `inner_cardinality` as 10000, that is, the unmodified size of `tenk2`. It might appear from inspection of the EXPLAIN output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on `tenk2`. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any WHERE clauses) is done in `src/backend/optimizer/util/plancat.c`. The generic logic for clause selectivities is in `src/backend/optimizer/path/clausesel.c`. The operator-specific selectivity functions are mostly found in `src/backend/utils/adt/selfuncs.c`.

### 65.2. Planner Statistics and Security

Access to the table `pg_statistic` is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate = operator to compare the constant in the query to the stored value. Thus the data in `pg_statistic` is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them...
to a different table), or accidentally leak them by showing their values in error messages, in either case
possibly exposing data from \texttt{pg\_statistic} to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning
a query, in order to be able to use stored statistics, the current user must either have \texttt{SELECT} privilege
on the table or the involved columns, or the operator used must be \texttt{LEAKPROOF} (more accurately, the
function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics
are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will
ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if
the user is reading from a security-barrier view, then the planner might wish to check the statistics of an
underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof
or the statistics will not be used. There is no direct feedback about that, except that the plan might be
suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user,
to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator
on one or more values from \texttt{pg\_statistic}. Thus the planner is permitted to use generic statistical
information, such as the fraction of null values or the number of distinct values in a column, regardless of
access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics
with user-defined operators should follow the same security rules. Consult the PostgreSQL source code
for guidance.
VIII. Appendixes
Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 9.5.21. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:) this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990118 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.

2. If the token is an alphabetic string, match up with possible strings:
   a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.
   b. If not found, search an internal table to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.

3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYYMMDD or YYYMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).

e. Otherwise the date field ordering is assumed to follow the `DateStyle` setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip: Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, suppose that the `TimeZone` parameter is set to `America/New_York`, consider

```
=> SELECT '2018-03-11 02:30'::timestamptz;
```

```
timestamptz
------------------------
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 02:30'::timestamptz;
```

```
timestamptz
------------------------
2018-11-04 02:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 2:30AM; there was 2:30AM EDT, and then an hour later after the reversion to standard time, there was 2:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the matter by specifying daylight-savings time:
Appendix B. Date/Time Support

```sql
=> SELECT '2018-11-04 02:30 EDT'::timestamptz;
 timestamptz
------------------------
 2018-11-04 01:30:00-05
(1 row)
```

This timestamp could validly be rendered as either 2:30 UTC-4 or 1:30 UTC-5; the timestamp output code chooses the latter.

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

### B.3. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

### B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in `.../share/timezonesets/` of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

timezone_abbreviations can be set to any file name found in `.../share/timezonesets/`, if the file’s name is entirely alphabetic. (The prohibition against non-alphabetic characters in timezone_abbreviations prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with #. Non-comment lines must have one of these formats:

- `zone_abbreviation offset`
- `zone_abbreviation offset D`
- `zone_abbreviation time_zone_name`
- `@INCLUDE file_name`
- `@OVERRIDE`
Appendix B. Date/Time Support

A *zone_abbreviation* is just the abbreviation being defined. An *offset* is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. D indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a *time_zone_name* can be given, referencing a zone name defined in the IANA timezone database. The zone’s definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn’t current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.

**Tip:** Using a simple integer *offset* is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The *@INCLUDE* syntax allows inclusion of another file in the `.../share/timezonesets/` directory. Inclusion can be nested, to a limited depth.

The *@OVERWRITE* syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file *Default* contains all the non-conflicting time zone abbreviations for most of the world. Additional files *Australia* and *India* are provided for those regions: these files first include the *Default* file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files *Africa.txt*, *America.txt*, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as *timezone_abbreviations* settings, because of the dot embedded in their names.

**Note:** If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

---

**Caution**

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the *Australia* configuration file defines `SAT` (for South Australian Standard Time). When this file is active, `SAT` will not be recognized as an abbreviation for Saturday.
B.5. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are con-
strained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows
the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before
that calendar was in use. This rule is known as the proleptic Gregorian calendar.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world
until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the
tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128
years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with
instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approximated as 365
+ 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical year to shift one
day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the following
rules:

Every year divisible by 4 is a leap year.
However, every year divisible by 100 is not a leap year.
However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years. By
contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that
15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal,
and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to
change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform was
observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2 September
1752 was followed by 14 September 1752. This is why Unix systems that have the cal program produce
the following:

```
$ cal 9 1752
   September 1752
   Su Mo Tu We Th Fr Sa
   1  2  3  4  5  6  7
   8  9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it would
be difficult and confusing to try to track the actual calendars that were in use in various places at various
times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates, even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian system. For example, the beginnings of the Chinese calendar can be traced back to the 14th century BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for determining festivals.

The Julian Date system is another type of calendar, unrelated to the Julian calendar though it is confusingly named similarly to that calendar. The Julian Date system was invented by the French scholar Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 January 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date counting is most often used by astronomers for labeling their nightly observations, and therefore a date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 designates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714 BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian dates for some internal datetime calculations), it does not observe the nicety of having dates run from noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.
Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 9.5.21. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, SELECT 55 AS CHECK, even though CHECK is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for PostgreSQL.
PostgreSQL supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, PostgreSQL conforms to at least 160. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed by a list of the features defined in SQL:2011 which are not yet supported in PostgreSQL. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

**Note:** Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

<table>

Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list records all source code changes as well. There is also a web interface that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 9.5.21

**Release date:** 2020-02-13

This release contains a variety of fixes from 9.5.20. For information about new features in the 9.5 major release, see Section E.22.

E.1.1. Migration to Version 9.5.21

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.20, see Section E.2.

E.1.2. Changes

- Avoid failure in logical decoding when a large transaction must be spilled into many separate temporary files (Amit Khandekar)
- Fix failure in logical replication publisher after a database crash and restart (Vignesh C)
- Avoid memory leak when there are no free dynamic shared memory slots (Thomas Munro)
- Ignore the `CONCURRENTLY` option when performing an index creation, drop, or rebuild on a temporary table (Michael Paquier, Heikki Linnakangas, Andres Freund)

This avoids strange failures if the temporary table has an `ON COMMIT` action. There is no benefit in using `CONCURRENTLY` for a temporary table anyway, since other sessions cannot access the table, making the extra processing pointless.

---

1. https://archives.postgresql.org/pgsql-committers/
Appendix E. Release Notes

- Fix possible failure when resetting expression indexes on temporary tables that are marked ON COMMIT DELETE ROWS (Tom Lane)
- Fix possible crash in BRIN index operations with box, range and inet data types (Heikki Linnakangas)
- Fix handling of deleted pages in GIN indexes (Alexander Korotkov)
  Avoid possible deadlocks, incorrect updates of a deleted page’s state, and failure to traverse through a recently-deleted page.
- Fix possible crash with a SubPlan (sub-SELECT) within a multi-row VALUES list (Tom Lane)
- Fix unlikely crash with pass-by-reference aggregate transition states (Andres Freund, Teodor Sigaev)
- Improve error reporting in to_date() and to_timestamp() (Tom Lane, Álvaro Herrera)
  Reports about incorrect month or day names in input strings could truncate the input in the middle of a multi-byte character, leading to an improperly encoded error message that could cause follow-on failures. Truncate at the next whitespace instead.
- Fix off-by-one result for EXTRACT(ISOYEAR FROM timestamp) for BC dates (Tom Lane)
- Avoid stack overflow in information_schema views when a self-referential view exists in the system catalogs (Tom Lane)
  A self-referential view can’t work; it will always result in infinite recursion. We handled that situation correctly when trying to execute the view, but not when inquiring whether it is automatically updatable.
- Improve performance of hash joins with very large inner relations (Thomas Munro)
- Fix edge-case crashes and misestimations in selectivity calculations for the <@ and @> range operators (Michael Paquier, Andrey Borodin, Tom Lane)
- Improve error reporting for attempts to use automatic updating of views with conditional INSTEAD rules (Dean Rasheed)
  This has never been supported, but previously the error was thrown only at execution time, so that it could be masked by planner errors.
- Prevent a composite type from being included in itself indirectly via a range type (Tom Lane, Julien Rouhaud)
- Fix error reporting for index expressions of prohibited types (Amit Langote)
- Fix dumping of views that contain only a VALUES list to handle cases where a view output column has been renamed (Tom Lane)
- Allow libpq to parse all GSS-related connection parameters even when the GSSAPI code hasn’t been compiled in (Tom Lane)
  This makes the behavior similar to our SSL support, where it was long ago deemed to be a good idea to always accept all the related parameters, even if some are ignored or restricted due to lack of the feature in a particular build.
- Fix incorrect handling of %b and %B format codes in ecpg’s PGTYPEStimestamp_fmt_asc() function (Tomas Vondra)
  Due to an off-by-one error, these codes would print the wrong month name, or possibly crash.
Appendix E. Release Notes

- Fix parallel pg_dump/pg_restore to more gracefully handle failure to create worker processes (Tom Lane)
- Prevent possible crash or lockup when attempting to terminate a parallel pg_dump/pg_restore run via a signal (Tom Lane)
- In pg_upgrade, look inside arrays and ranges while searching for non-upgradable data types in tables (Tom Lane)
- Apply more thorough syntax checking to createuser's --connection-limit option (Álvaro Herrera)
- In contrib/dict_int, reject maxlen settings less than one (Tomas Vondra)
  This prevents a possible crash with silly settings for that parameter.
- Disallow NULL category values in contrib/tablefunc's crosstab() function (Joe Conway)
  This case never worked usefully, and it would crash on some platforms.
- Mark some timeout and statistics-tracking GUC variables as PGDLLIMPORT, to allow extensions to access them on Windows (Pascal Legrand)
  This applies to idle_in_transaction_session_timeout, lock_timeout, statement_timeout, track_activities, track_counts, and track_functions.
- Fix race condition that led to delayed delivery of interprocess signals on Windows (Amit Kapila)
  This caused visible timing oddities in NOTIFY, and perhaps other misbehavior.
- On Windows, retry a few times after an ERROR_ACCESS_DENIED file access failure (Alexander Lakhin, Tom Lane)
  This helps cope with cases where a file open attempt fails because the targeted file is flagged for deletion but not yet actually gone. pg_ctl, for example, frequently failed with such an error when probing to see if the postmaster had shut down yet.

E.2. Release 9.5.20

Release date: 2019-11-14

This release contains a variety of fixes from 9.5.19. For information about new features in the 9.5 major release, see Section E.22.

E.2.1. Migration to Version 9.5.20

A dump/restore is not required for those running 9.5.X.

However, if you use the contrib/intarray extension with a GiST index, and you rely on indexed searches for the <@ operator, see the entry below about that.

Also, if you are upgrading from a version earlier than 9.5.13, see Section E.9.
E.2.2. Changes

- Disallow changing a multiply-inherited column’s type if not all parent tables were changed (Tom Lane)
  Previously, this was allowed, whereupon queries on the now-out-of-sync parent would fail.
- Prevent `VACUUM` from trying to freeze an old multixact ID involving a still-running transaction (Nathan Bossart, Jeremy Schneider)
  This case would lead to `VACUUM` failing until the old transaction terminates.
- Ensure that offset expressions in `WINDOW` clauses are processed when a query’s expressions are manipulated (Andrew Gierth)
  This oversight could result in assorted failures when the offsets are nontrivial expressions. One example is that a function parameter reference in such an expression would fail if the function was inlined.
- Fix handling of whole-row variables in `WITH CHECK OPTION` expressions and row-level-security policy expressions (Andres Freund)
  Previously, such usage might result in bogus errors about row type mismatches.
- Avoid postmaster failure if a parallel query requests a background worker when no postmaster child process array slots remain free (Tom Lane)
- Prevent possible double-free if a `BEFORE UPDATE` trigger returns the old tuple as-is, and it is not the last such trigger (Thomas Munro)
- Provide a relevant error context line when an error occurs while setting GUC parameters during parallel worker startup (Thomas Munro)
- In serializable mode, ensure that row-level predicate locks are acquired on the correct version of the row (Thomas Munro, Heikki Linnakangas)
  If the visible version of the row is HOT-updated, the lock might be taken on its now-dead predecessor, resulting in subtle failures to guarantee serialization.
- Ensure that `fsync()` is applied only to files that are opened read/write (Andres Freund, Michael Paquier)
  Some code paths tried to do this after opening a file read-only, but on some platforms that causes “bad file descriptor” or similar errors.
- Allow encoding conversion to succeed on longer strings than before (Álvaro Herrera, Tom Lane)
  Previously, there was a hard limit of 0.25GB on the input string, but now it will work as long as the converted output is not over 1GB.
- Allow `realloc()` to give back space when a large chunk is reduced in size (Tom Lane)
- Ensure that temporary WAL and history files are removed at the end of archive recovery (Sawada Masahiko)
- Avoid failure in archive recovery if `recovery_min_apply_delay` is enabled (Fujii Masao)
  `recovery_min_apply_delay` is not typically used in this configuration, but it should work.
- Avoid unwanted delay during shutdown of a logical replication walsender (Craig Ringer, Álvaro Herrera)
- Correctly time-stamp replication messages for logical decoding (Jeff Janes)
This oversight resulted, for example, in `pg_stat_subscription.last_msg_send_time` usually reading as NULL.

- In logical decoding, ensure that sub-transactions are correctly accounted for when reconstructing a snapshot (Masahiko Sawada)
  This error leads to assertion failures; it’s unclear whether any bad effects exist in production builds.
- Fix race condition during backend exit, when the backend process has previously waited for synchronous replication to occur (Dongming Liu)
- **Fix `ALTER SYSTEM` to cope with duplicate entries in** `postgresql.auto.conf` (Ian Barwick)
  `ALTER SYSTEM` itself will not generate such a state, but external tools that modify `postgresql.auto.conf` could do so. Duplicate entries for the target variable will now be removed, and then the new setting (if any) will be appended at the end.
- Reject include directives with empty file names in configuration files, and report include-file recursion more clearly (Ian Barwick, Tom Lane)
- Avoid logging complaints about abandoned connections when using PAM authentication (Tom Lane)
  libpq-based clients will typically make two connection attempts when a password is required, since they don’t prompt their user for a password until their first connection attempt fails. Therefore the server is coded not to generate useless log spam when a client closes the connection upon being asked for a password. However, the PAM authentication code hadn’t gotten that memo, and would generate several messages about a phantom authentication failure.
- Fix some cases where an incomplete date specification is not detected in `time with time zone` input (Alexander Lakhin)
  If a time zone with a time-varying UTC offset is specified, then a date must be as well, so that the offset can be resolved. Depending on the syntax used, this check was not enforced in some cases, allowing bogus output to be produced.
- Fix misbehavior of `bitshiftright()` (Tom Lane)
  The bitstring right shift operator failed to zero out padding space that exists in the last byte of the result when the bitstring length is not a multiple of 8. While invisible to most operations, any nonzero bits there would result in unexpected comparison behavior, since bitstring comparisons don’t bother to ignore the extra bits, expecting them to always be zero.

  If you have inconsistent data as a result of saving the output of `bitshiftright()` in a table, it’s possible to fix it with something like
  ```sql
  UPDATE mytab SET bitcol = - (~bitcol) WHERE bitcol != - (~bitcol);
  ```
- Fix detection of edge-case integer overflow in interval multiplication (Yuya Watari)
- Fix incorrect compression logic for GIN posting lists (Heikki Linnakangas)
  A GIN posting list item can require 7 bytes if the distance between adjacent indexed TIDs exceeds 16TB. One step in the logic was out of sync with that, and might try to write the value into a 6-byte buffer. In principle this could cause a stack overrun, but on most architectures it’s likely that the next byte would be unused alignment padding, making the bug harmless. In any case the bug would be very difficult to hit.
- Fix handling of infinity, NaN, and NULL values in KNN-GiST (Alexander Korotkov)
Appendix E. Release Notes

The query’s output order could be wrong (different from a plain sort’s result) if some distances computed for non-null column values are infinity or NaN.

- Fix handling of searches for NULL in KNN-SP-GiST (Nikita Glukhov)
- On Windows, recognize additional spellings of the “Norwegian (Bokmål)” locale name (Tom Lane)
- Avoid compile failure if an ECPG client includes `ecpglib.h` while having `ENABLE_NLS` defined (Tom Lane)

This risk was created by a misplaced declaration: `ecpg gettext()` should not be visible to client code.

- In psql, resynchronize internal state about the server after an unexpected connection loss and successful reconnection (Peter Billen, Tom Lane)

Ordinarily this is unnecessary since the state would be the same anyway. But it can matter in corner cases, such as where the connection might lead to one of several servers. This change causes psql to re-issue any interactive messages that it would have issued at startup, for example about whether SSL is in use.

- Avoid platform-specific null pointer dereference in psql (Quentin Rameau)
- Fix `pg_dump`’s handling of circular dependencies in views (Tom Lane)

In some cases a view may depend on an object that `pg_dump` needs to dump later than the view; the most common example is that a query using `GROUP BY` on a primary-key column may be semantically invalid without the primary key. This is now handled by emitting a dummy `CREATE VIEW` command that just establishes the view’s column names and types, and then later emitting `CREATE OR REPLACE VIEW` with the full view definition. Previously, the dummy definition was actually a `CREATE TABLE` command, and this was automagically converted to a view by a later `CREATE RULE` command. The new approach has been used successfully in PostgreSQL version 10 and later. We are back-patching it into older releases now because of reports that the previous method causes bogus error messages about the view’s replica identity status. This change also avoids problems when trying to use the `--clean` option during a restore involving such a view.

- In `pg_dump`, ensure stable output order for similarly-named triggers and row-level-security policy objects (Benjie Gillam)

Previously, if two triggers on different tables had the same names, they would be sorted in OID-based order, which is less desirable than sorting them by table name. Likewise for RLS policies.

- Fix `pg_dump` to work again with pre-8.3 source servers (Tom Lane)

A previous fix caused `pg_dump` to always try to query `pg_opfamily`, but that catalog doesn’t exist before version 8.3.

- In `pg_restore`, treat `--` as meaning “output to stdout” (Álvaro Herrera)

This synchronizes `pg_restore`’s behavior with some other applications, and in particular makes `pre-v12` branches act similarly to version 12’s `pg_restore`, simplifying creation of dump/restore scripts that work across multiple PostgreSQL versions. Before this change, `pg_restore` interpreted such a switch as meaning “output to a file named ‘–’”, but few people would want that.

- Improve `pg_upgrade`’s checks for the use of a data type that has changed representation, such as `line` (Tomas Vondra)
The previous coding could be fooled by cases where the data type of interest underlies a stored column of a domain or composite type.

- Detect file read errors during pg_basebackup (Jeevan Chalke)
- In pg_rewind with an online source cluster, disable timeouts, much as pg_dump does (Alexander Kukushkin)
- Fix failure in pg_waldump with the -s option, when a continuation WAL record ends exactly at a page boundary (Andrey Lepikhov)
- In pg_waldump, include the newitemoff field in btree page split records (Peter Geoghegan)
- In pg_waldump with the --bkp-details option, avoid emitting extra newlines for WAL records involving full-page writes (Andres Freund)
- Fix small memory leak in pg_waldump (Andres Freund)
- Fix vacuumdb with a high --jobs option to handle running out of file descriptors better (Michael Paquier)
- Fix contrib/intarray’s GiST opclasses to not fail for empty arrays with <@ (Tom Lane)
  
  A clause like array_column <@ constant_array is considered indexable, but the index search may not find empty array values; of course, such entries should trivially match the search.

  The only practical back-patchable fix for this requires making <@ index searches scan the whole index, which is what this patch does. This is unfortunate: it means that the query performance is likely worse than a plain sequential scan would be.

  Applications whose performance is adversely impacted by this change have a couple of options. They could switch to a GIN index, which doesn’t have this bug, or they could replace array_column <@ constant_array with array_column <@ constant_array AND array_column & constant_array. That will provide about the same performance as before, and it will find all non-empty subsets of the given constant array, which is all that could reliably be expected of the query before.

- Allow configure --with-python to succeed when only python3 or only python2 can be found (Peter Eisenstraut, Tom Lane)
  
  Search for python, then python3, then python2, so that configure can succeed in the increasingly-more-common situation where there is no executable named simply python. It’s still possible to override this choice by setting the PYTHON environment variable.

- Fix configure’s test for presence of libperl so that it works on recent Red Hat releases (Tom Lane)
  
  Previously, it could fail if the user sets CFLAGS to -00.

- Ensure correct code generation for spinlocks on PowerPC (Noah Misch)
  
  The previous spinlock coding allowed the compiler to select register zero for use with an assembly instruction that does not accept that register, causing a build failure. We have seen only one long-ago report that matches this bug, but it could cause problems for people trying to build modified PostgreSQL code or use atypical compiler options.

- On PowerPC, avoid depending on the xlc compiler’s __fetch_and_add() function (Noah Misch)
  
  xlc 13 and newer interpret this function in a way incompatible with our usage, resulting in an unusable build of PostgreSQL. Fix by using custom assembly code instead.
• On AIX, don’t use the compiler option -qscremsg (Noah Misch)
  This avoids an internal compiler error with xlc v16.1.0, with little consequence other than changing the format of compiler error messages.
• Fix MSVC build process to cope with spaces in the file path of OpenSSL (Andrew Dunstan)
• Update time zone data files to tzdata release 2019c for DST law changes in Fiji and Norfolk Island, plus historical corrections for Alberta, Austria, Belgium, British Columbia, Cambodia, Hong Kong, Indiana (Perry County), Kaliningrad, Kentucky, Michigan, Norfolk Island, South Korea, and Turkey.

E.3. Release 9.5.19

Release date: 2019-08-08
This release contains a variety of fixes from 9.5.18. For information about new features in the 9.5 major release, see Section E.22.

E.3.1. Migration to Version 9.5.19

A dump/restore is not required for those running 9.5.X.
However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

E.3.2. Changes

• Require schema qualification to cast to a temporary type when using functional cast syntax (Noah Misch)
  We have long required invocations of temporary functions to explicitly specify the temporary schema, that is `pg_temp.func_name(args)`. Require this as well for casting to temporary types using functional notation, for example `pg_temp.type_name(arg)`. Otherwise it’s possible to capture a function call using a temporary object, allowing privilege escalation in much the same ways that we blocked in CVE-2007-2138. (CVE-2019-10208)
• Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when altering multiple columns’ types in one command (Tom Lane)
  This fixes a regression introduced in the most recent minor releases: indexes using the altered columns were not processed correctly, leading to strange failures during `ALTER TABLE`.
• Avoid using unnecessary sort steps for some queries with `GROUPING SETS` (Andrew Gierth, Richard Guo)
• Fix mishandling of multi-column foreign keys when rebuilding a foreign key constraint (Tom Lane)
  `ALTER TABLE` could make an incorrect decision about whether revalidation of a foreign key is necessary, if not all columns of the key are of the same type. It seems likely that the error would always have been in the conservative direction, that is revalidating unnecessarily.
• Prevent incorrect canonicalization of date ranges with infinity endpoints (Laurenz Albe)
  It’s incorrect to try to convert an open range to a closed one or vice versa by incrementing or decrementing the endpoint value, if the endpoint is infinite; so leave the range alone in such cases.
• Fix loss of fractional digits when converting very large money values to numeric (Tom Lane)
• Fix spinlock assembly code for MIPS CPUs so that it works on MIPS r6 (YunQiang Su)
• Make libpq ignore carriage return (\r) in connection service files (Tom Lane, Michael Paquier)
  In some corner cases, service files containing Windows-style newlines could be mis-parsed, resulting in connection failures.
• Fix pg_dump to ensure that custom operator classes are dumped in the right order (Tom Lane)
  If a user-defined opclass is the subtype opclass of a user-defined range type, related objects were dumped in the wrong order, producing an unrestorable dump. (The underlying failure to handle opclass dependencies might manifest in other cases too, but this is the only known case.)
• Fix contrib/passwordcheck to coexist with other users of check_password_hook (Michael Paquier)
• Fix contrib/sepgsql tests to work under recent SELinux releases (Mike Palmiotto)
• Reduce stderr output from pg_upgrade’s test script (Tom Lane)
• Support building Postgres with Microsoft Visual Studio 2019 (Haribabu Kommi)
• In Visual Studio builds, honor WindowsSDKVersion environment variable, if that’s set (Peifeng Qiu)
  This fixes build failures in some configurations.
• Support OpenSSL 1.1.0 and newer in Visual Studio builds (Juan José Santamaría Flecha, Michael Paquier)
• Allow make options to be passed down to gmake when non-GNU make is invoked at the top level (Thomas Munro)
• Avoid choosing localtime or posixrules as TimeZone during initdb (Tom Lane)
  In some cases initdb would choose one of these artificial zone names over the “real” zone name. Prefer any other match to the C library’s timezone behavior over these two.
• Adjust pg_timezone_names view to show the Factory time zone if and only if it has a short abbreviation (Tom Lane)
  Historically, IANA set up this artificial zone with an “abbreviation” like Local time zone must be set--see zic manual page. Modern versions of the tzdb database show -00 instead, but some platforms alter the data to show one or another of the historical phrases. Show this zone only if it uses the modern abbreviation.
• Sync our copy of the timezone library with IANA tzcode release 2019b (Tom Lane)
  This adds support for zic’s new -b slim option to reduce the size of the installed zone files. We are not currently using that, but may enable it in future.
• Update time zone data files to tzdata release 2019b for DST law changes in Brazil, plus historical corrections for Hong Kong, Italy, and Palestine.
Appendix E. Release Notes

E.4. Release 9.5.18

Release date: 2019-06-20

This release contains a variety of fixes from 9.5.17. For information about new features in the 9.5 major release, see Section E.22.

E.4.1. Migration to Version 9.5.18

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

E.4.2. Changes

• Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when the table has a partial exclusion constraint (Tom Lane)

• Fix failure of `COMMENT` command for comments on domain constraints (Daniel Gustafsson, Michael Paquier)

• Fix incorrect printing of queries with duplicate join names (Philip Dubé)
  
  This oversight caused a dump/restore failure for views containing such queries.

• Fix misoptimization of `{1,1}` quantifiers in regular expressions (Tom Lane)
  
  Such quantifiers were treated as no-ops and optimized away; but the documentation specifies that they impose greediness, or non-greediness in the case of the non-greedy variant `{1,1}?`, on the subexpression they’re attached to, and this did not happen. The misbehavior occurred only if the subexpression contained capturing parentheses or a back-reference.

• Avoid possible failures while initializing a new process’s `pg_stat_activity` data (Tom Lane)
  
  Certain operations that could fail, such as converting strings extracted from an SSL certificate into the database encoding, were being performed inside a critical section. Failure there would result in database-wide lockup due to violating the access protocol for shared `pg_stat_activity` data.

• Fix race condition in check to see whether a pre-existing shared memory segment is still in use by a conflicting postmaster (Tom Lane)

• Avoid attempting to do database accesses for parameter checking in processes that are not connected to a specific database (Vignesh C, Andres Freund)
  
  This error could result in failures like “cannot read pg_class without having selected a database”.

• Avoid possible hang in libpq if using SSL and OpenSSL’s pending-data buffer contains an exact multiple of 256 bytes (David Binderman)

• Improve initdb’s handling of multiple equivalent names for the system time zone (Tom Lane, Andrew Gierth)
  
  Make initdb examine the `/etc/zoneinfo` symbolic link, if that exists, to break ties between equivalent names for the system time zone. This makes initdb more likely to select the time zone name
that the user would expect when multiple identical time zones exist. It will not change the behavior if /etc/localtime is not a symlink to a zone data file, nor if the time zone is determined from the TZ environment variable.

Separately, prefer UTC over other spellings of that time zone, when neither TZ nor /etc/localtime provide a hint. This fixes an annoyance introduced by tzdata 2019a’s change to make the UCT and UTC zone names equivalent: initdb was then preferring UCT, which almost nobody wants.

- Fix misleading error reports from reindexdb (Julien Rouhaud)
- Ensure that vacuumdb returns correct status if an error occurs while using parallel jobs (Julien Rouhaud)
- In contrib/postgres_fdw, account for possible data modifications by local BEFORE ROW UPDATE triggers (Shohei Mochizuki)
  If a trigger modified a column that was otherwise not changed by the UPDATE, the new value was not transmitted to the remote server.
- On Windows, avoid failure when the database encoding is set to SQL_ASCII and we attempt to log a non-ASCII string (Noah Misch)
  The code had been assuming that such strings must be in UTF-8, and would throw an error if they didn’t appear to be validly encoded. Now, just transmit the untranslated bytes to the log.
- Make PL/pgSQL’s header files C++-safe (George Tarasov)

---

**E.5. Release 9.5.17**

**Release date:** 2019-05-09

This release contains a variety of fixes from 9.5.16. For information about new features in the 9.5 major release, see Section E.22.

**E.5.1. Migration to Version 9.5.17**

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

**E.5.2. Changes**

- Prevent row-level security policies from being bypassed via selectivity estimators (Dean Rasheed)

Some of the planner’s selectivity estimators apply user-defined operators to values found in pg_statistic (e.g., most-common values). A leaky operator therefore can disclose some of the entries in a data column, even if the calling user lacks permission to read that column. In CVE-2017-7484 we added restrictions to forestall that, but we failed to consider the effects of row-level security. A user who has SQL permission to read a column, but who is forbidden to see certain rows due to RLS policy, might still learn something about those rows’ contents via a leaky
operator. This patch further tightens the rules, allowing leaky operators to be applied to statistics data only when there is no relevant RLS policy. (CVE-2019-10130)

- Fix behavior for an UPDATE or DELETE on an inheritance tree or partitioned table in which every table can be excluded (Amit Langote, Tom Lane)

  In such cases, the query did not report the correct set of output columns when a RETURNING clause was present, and if there were any statement-level triggers that should be fired, it didn’t fire them.

- Fix handling of explicit DEFAULT items in an INSERT ... VALUES command with multiple VALUES rows, if the target relation is an updatable view (Amit Langote, Dean Rasheed)

  When the updatable view has no default for the column but its underlying table has one, a single-row INSERT ... VALUES will use the underlying table’s default. In the multi-row case, however, NULL was always used. Correct it to act like the single-row case.

- Fix CREATE VIEW to allow zero-column views (Ashutosh Sharma)

  We should allow this for consistency with allowing zero-column tables. Since a table can be converted to a view, zero-column views could be created even with the restriction in place, leading to dump/reload failures.

- Add missing support for CREATE TABLE IF NOT EXISTS ... AS EXECUTE ... (Andreas Karlsson)

  The combination of IF NOT EXISTS and EXECUTE should work, but the grammar omitted it.

- Ensure that sub-SELECTs appearing in row-level-security policy expressions are executed with the correct user’s permissions (Dean Rasheed)

  Previously, if the table having the RLS policy was accessed via a view, such checks might be executed as the user calling the view, not as the view owner as they should be.

- Accept XML documents as valid values of type xml when xmloption is set to content, as required by SQL:2006 and later (Chapman Flack)

  Previously PostgreSQL followed the SQL:2003 definition, which doesn’t allow this. But that creates a serious problem for dump/restore: there is no setting of xmloption that will accept all valid XML data. Hence, switch to the 2006 definition.

  pg_dump is also modified to emit SET xmloption = content while restoring data, ensuring that dump/restore works even if the prevailing setting is document.

- Improve server’s startup-time checks for whether a pre-existing shared memory segment is still in use (Noah Misch)

  The postmaster is now more likely to detect that there are still active processes from a previous postmaster incarnation, even if the postmaster.pid file has been removed.

- Fix incompatibility of GIN-index WAL records (Alexander Korotkov)

  A fix applied in February’s minor releases was not sufficiently careful about backwards compatibility, leading to problems if a standby server of that vintage reads GIN page-deletion WAL records generated by a primary server of a previous minor release.

- Tolerate EINVAL and ENOSYS error results, where appropriate, for fsync and sync_file_range calls (Thomas Munro, James Sewell)
Appendix E. Release Notes

The previous change to panic on file synchronization failures turns out to have been excessively paranoic for certain cases where a failure is predictable and essentially means “operation not supported”.

- Fix “failed to build any $N$-way joins” planner failures with lateral references leading out of FULL outer joins (Tom Lane)
- Check the appropriate user’s permissions when enforcing rules about letting a leaky operator see pg_statistic data (Dean Rasheed)
  
  When an underlying table is being accessed via a view, consider the privileges of the view owner while deciding whether leaky operators may be applied to the table’s statistics data, rather than the privileges of the user making the query. This makes the planner’s rules about what data is visible match up with the executor’s, avoiding unnecessarily-poor plans.
- Avoid $O(N^2)$ performance issue when rolling back a transaction that created many tables (Tomas Vondra)
- Fix race conditions in management of dynamic shared memory (Thomas Munro)
  
  These could lead to “dsa_area could not attach to segment” or “cannot unpin a segment that is not pinned” errors.
- Fix race condition in which a hot-standby postmaster could fail to shut down after receiving a smart-shutdown request (Tom Lane)
- Fix possible crash when pg_identify_object_as_address() is given invalid input (Álvaro Herrera)
- Tighten validation of encoded SCRAM-SHA-256 and MD5 passwords (Jonathan Katz)
  
  A password string that had the right initial characters could be mistaken for one that is correctly hashed into SCRAM-SHA-256 or MD5 format. The password would be accepted but would be unusable later.
- Fix handling of lc_time settings that imply an encoding different from the database’s encoding (Juan José Santamaría Flecha, Tom Lane)
  
  Localized month or day names that include non-ASCII characters previously caused unexpected errors or wrong output in such locales.
- Fix incorrect operator_precedence_warning checks involving unary minus operators (Rikard Falkeborn)
- Disallow NaN as a value for floating-point server parameters (Tom Lane)
- Rearrange REINDEX processing to avoid assertion failures when reindexing individual indexes of pg_class (Andres Freund, Tom Lane)
- Fix planner assertion failure for parameterized dummy paths (Tom Lane)
- Insert correct test function in the result of SnapBuildInitialSnapshot() (Antonin Houska)
  
  No core code cares about this, but some extensions do.
- Fix intermittent “could not reattach to shared memory” session startup failures on Windows (Noah Misch)
  
  A previously unrecognized source of these failures is creation of thread stacks for a process’s default thread pool. Arrange for such stacks to be allocated in a different memory region.
- Fix error detection in directory scanning on Windows (Konstantin Knizhnik)
Errors, such as lack of permissions to read the directory, were not detected or reported correctly; instead the code silently acted as though the directory were empty.

- Fix grammar problems in ecpg (Tom Lane)
  A missing semicolon led to mistranslation of `SET variable = DEFAULT` (but not `SET variable TO DEFAULT`) in ecpg programs, producing syntactically invalid output that the server would reject. Additionally, in a `DROP TYPE` or `DROP DOMAIN` command that listed multiple type names, only the first type name was actually processed.

- Sync ecpg’s syntax for `CREATE TABLE AS` with the server’s (Daisuke Higuchi)

- Fix possible buffer overruns in ecpg’s processing of include filenames (Liu Huailing, Fei Wu)

- Avoid crash in contrib/vacuumlo if an `lo_unlink()` call failed (Tom Lane)

- Sync our copy of the timezone library with IANA tzcode release 2019a (Tom Lane)
  This corrects a small bug in zic that caused it to output an incorrect year-2440 transition in the `Africa/Casablanca` zone, and adds support for zic’s new `-r` option.

- Update time zone data files to tzdata release 2019a for DST law changes in Palestine and Metlakatla, plus historical corrections for Israel.

  `Etc/UCT` is now a backward-compatibility link to `Etc/UTC`, instead of being a separate zone that generates the abbreviation `UCT`, which nowadays is typically a typo. PostgreSQL will still accept `UCT` as an input zone abbreviation, but it won’t output it.

### E.6. Release 9.5.16

**Release date:** 2019-02-14

This release contains a variety of fixes from 9.5.15. For information about new features in the 9.5 major release, see Section E.22.

#### E.6.1. Migration to Version 9.5.16

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

#### E.6.2. Changes

- By default, panic instead of retrying after `fsync()` failure, to avoid possible data corruption (Craig Ringer, Thomas Munro)

  Some popular operating systems discard kernel data buffers when unable to write them out, reporting this as `fsync()` failure. If we reissue the `fsync()` request it will succeed, but in fact the data has been lost, so continuing risks database corruption. By raising a panic condition instead, we can replay from
Appendix E. Release Notes

WAL, which may contain the only remaining copy of the data in such a situation. While this is surely ugly and inefficient, there are few alternatives, and fortunately the case happens very rarely.

A new server parameter data_sync_retry has been added to control this; if you are certain that your kernel does not discard dirty data buffers in such scenarios, you can set data_sync_retry to on to restore the old behavior.

• Include each major release branch’s release notes in the documentation for only that branch, rather than that branch and all later ones (Tom Lane)

The duplication induced by the previous policy was getting out of hand. Our plan is to provide a full archive of release notes on the project’s web site, but not duplicate it within each release.

• Avoid possible deadlock when acquiring multiple buffer locks (Nishant Fnu)

• Avoid deadlock between hot-standby queries and replay of GIN index page deletion (Alexander Krotkov)

• Fix possible crashes in logical replication when index expressions or predicates are in use (Peter Eisentraut)

• Avoid useless and expensive logical decoding of TOAST data during a table rewrite (Tomas Vondra)

• Fix logic for stopping a subset of WAL senders when synchronous replication is enabled (Paul Guo, Michael Paquier)

• Avoid possibly writing an incorrect replica identity field in a tuple deletion WAL record (Stas Kelvich)

• Make the archiver prioritize WAL history files over WAL data files while choosing which file to archive next (David Steele)

• Fix possible crash in UPDATE with a multiple SET clause using a sub-SELECT as source (Tom Lane)

• Avoid crash if libxml2 returns a null error message (Sergio Conde Gómez)

• Fix spurious grouping-related parser errors caused by inconsistent handling of collation assignment (Andrew Gierth)

In some cases, expressions that should be considered to match were not seen as matching, if they included operations on collatable data types.

• Check whether the comparison function underlying LEAST() or GREATEST() is leakproof, rather than just assuming it is (Tom Lane)

Actual information leaks from btree comparison functions are typically hard to provoke, but in principle they could happen.

• Fix incorrect planning of queries in which a lateral reference must be evaluated at a foreign table scan (Tom Lane)

• Fix corner-case underestimation of the cost of a merge join (Tom Lane)

The planner could prefer a merge join when the outer key range is much smaller than the inner key range, even if there are so many duplicate keys on the inner side that this is a poor choice.

• Avoid O(N^2) planning time growth when a query contains many thousand indexable clauses (Tom Lane)

• Improve ANALYZE’s handling of concurrently-updated rows (Jeff Janes, Tom Lane)
Previously, rows deleted by an in-progress transaction were omitted from `ANALYZE`’s sample, but this has been found to lead to more inconsistency than including them would do. In effect, the sample now corresponds to an MVCC snapshot as of `ANALYZE`’s start time.

- **Make `TRUNCATE` ignore inheritance child tables that are temporary tables of other sessions** (Amit Langote, Michael Paquier)

  This brings `TRUNCATE` into line with the behavior of other commands. Previously, such cases usually ended in failure.

- **Fix `TRUNCATE` to update the statistics counters for the right table** (Tom Lane)

  If the truncated table had a TOAST table, that table’s counters were reset instead.

- **Allow `UNLISTEN` in hot-standby mode** (Shay Rojansky)

  This is necessarily a no-op, because `LISTEN` isn’t allowed in hot-standby mode; but allowing the dummy operation simplifies session-state-reset logic in clients.

- **Fix missing role dependencies in some schema and data type permissions lists** (Tom Lane)

  In some cases it was possible to drop a role to which permissions had been granted. This caused no immediate problem, but a subsequent dump/reload or upgrade would fail, with symptoms involving attempts to grant privileges to all-numeric role names.

- **Ensure relation caches are updated properly after renaming constraints** (Amit Langote)

- **Make autovacuum more aggressive about removing leftover temporary tables, and also remove leftover temporary tables during `DISCARD TEMP`** (Álvaro Herrera)

  This helps ensure that remnants from a crashed session are cleaned up more promptly.

- **Prevent empty GIN index pages from being reclaimed too quickly, causing failures of concurrent searches** (Andrey Borodin, Alexander Korotkov)

- **Fix edge-case failures in float-to-integer coercions** (Andrew Gierth, Tom Lane)

  Values very slightly above the maximum valid integer value might not be rejected, and then would overflow, producing the minimum valid integer instead. Also, values that should round to the minimum or maximum integer value might be incorrectly rejected.

- **Disallow setting `client_min_messages` higher than `ERROR`** (Jonah Harris, Tom Lane)

  Previously, it was possible to set this variable to `FATAL` or `PANIC`, which had the effect of suppressing transmission of ordinary error messages to the client. However, that’s contrary to guarantees that are given in the PostgreSQL wire protocol specification, and it caused some clients to become very confused. In released branches, fix this by silently treating such settings as meaning `ERROR` instead. Version 12 and later will reject those alternatives altogether.

- **Fix ecpglib to use `uselocale()` or `_configthreadlocale()` in preference to `setlocale()`** (Michael Meskes, Tom Lane)

  Since `setlocale()` is not thread-local, and might not even be thread-safe, the previous coding caused problems in multi-threaded ecpg applications.

- **Fix incorrect results for numeric data passed through an ecpg SQLDA (SQL Descriptor Area)** (Daisuke Higuchi)

  Values with leading zeroes were not copied correctly.

- **Fix psql’s `\g target` meta-command to work with `COPY TO STDOUT`** (Daniel Vérié)
Previously, the *target* option was ignored, so that the copy data always went to the current query output target.

- Make psql’s LaTeX output formats render special characters properly (Tom Lane)
  Backslash and some other ASCII punctuation characters were not rendered correctly, leading to document syntax errors or wrong characters in the output.

- Fix pg_dump’s handling of materialized views with indirect dependencies on primary keys (Tom Lane)
  This led to mis-labeling of such views’ dump archive entries, causing harmless warnings about “archive items not in correct section order”; less harmlessly, selective-restore options depending on those labels, such as --section, might misbehave.

- Avoid null-pointer-dereference crash on some platforms when pg_dump or pg_restore tries to report an error (Tom Lane)

- Fix contrib/hstore to calculate correct hash values for empty hstore values that were created in version 8.4 or before (Andrew Gierth)
  The previous coding did not give the same result as for an empty hstore value created by a newer version, thus potentially causing wrong results in hash joins or hash aggregation. It is advisable to reindex any hash indexes built on hstore columns, if the table might contain data that was originally stored as far back as 8.4 and was never dumped/reloaded since then.

- Avoid crashes and excessive runtime with large inputs to contrib/intarray’s gist__int_ops index support (Andrew Gierth)

- Adjust configure’s selection of threading-related compiler flags and libraries to match what later PostgreSQL releases do (Tom Lane)
  The coding previously used in the 9.4 and 9.5 branches fails outright on some newer platforms, so sync it with what 9.6 and later have been doing.

- Support new Makefile variables PG_CFLAGS, PG_CXXFLAGS, and PG_LDFLAGS in pgxs builds (Christoph Berg)
  This simplifies customization of extension build processes.

- Fix Perl-coded build scripts to not assume “.” is in the search path, since recent Perl versions don’t include that (Andrew Dunstan)

- Fix server command-line option parsing problems on OpenBSD (Tom Lane)

- Update time zone data files to tzdata release 2018i for DST law changes in Kazakhstan, Metlakatla, and Sao Tome and Principe. Kazakhstan’s Qyzylorda zone is split in two, creating a new zone Asia/Qostanay, as some areas did not change UTC offset. Historical corrections for Hong Kong and numerous Pacific islands.

### E.7. Release 9.5.15

**Release date:** 2018-11-08

This release contains a variety of fixes from 9.5.14. For information about new features in the 9.5 major release, see Section E.22.
E.7.1. Migration to Version 9.5.15

A dump/restore is not required for those running 9.5.X.
However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

E.7.2. Changes

- Fix corner-case failures in `has_foo_privilege()` family of functions (Tom Lane)
  Return NULL rather than throwing an error when an invalid object OID is provided. Some of these functions got that right already, but not all. `has_column_privilege()` was additionally capable of crashing on some platforms.
- Avoid O(N^2) slowdown in regular expression match/split functions on long strings (Andrew Gierth)
- Fix parsing of standard multi-character operators that are immediately followed by a comment or + or - (Andrew Gierth)
  This oversight could lead to parse errors, or to incorrect assignment of precedence.
- Avoid O(N^3) slowdown in lexer for long strings of + or - characters (Andrew Gierth)
- Fix mis-execution of SubPlans when the outer query is being scanned backwards (Andrew Gierth)
- Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor (Tom Lane)
  A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior if rewound to an earlier relation.
- Fix `EvalPlanQual` to handle conditionally-executed InitPlans properly (Andrew Gierth, Tom Lane)
  This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained code such as an uncorrelated sub-`SELECT` inside a `CASE` construct.
- Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane, Kenji Uno)
  This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.
- Ensure that sequences owned by a foreign table are processed by `ALTER OWNER` on the table (Peter Eisentraut)
  The ownership change should propagate to such sequences as well, but this was missed for foreign tables.
- Ensure that the server will process already-received `NOTIFY` and `SIGTERM` interrupts before waiting for client input (Jeff Janes, Tom Lane)
- Fix over-allocation of space for `array_out()`’s result string (Keiichi Hirobe)
- Fix memory leak in repeated SP-GiST index scans (Tom Lane)
  This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.
Appendix E. Release Notes

- Ensure that `ApplyLogicalMappingFile()` closes the mapping file when done with it (Tomas Vondra)
  Previously, the file descriptor was leaked, eventually resulting in failures during logical decoding.
- Fix logical decoding to handle cases where a mapped catalog table is repeatedly rewritten, e.g. by `VACUUM FULL` (Andres Freund)
- Prevent starting the server with `wal_level` set to too low a value to support an existing replication slot (Andres Freund)
- Avoid crash if a utility command causes infinite recursion (Tom Lane)
- When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the master (Michael Paquier, Konstantin Knizhnik)
- Fix event triggers to handle nested `ALTER TABLE` commands (Michael Paquier, Álvaro Herrera)
- Propagate parent process’s transaction and statement start timestamps to parallel workers (Konstantin Knizhnik)
  This prevents misbehavior of functions such as `transaction_timestamp()` when executed in a worker.
- Fix WAL file recycling logic to work correctly on standby servers (Michael Paquier)
  Depending on the setting of `archive_mode`, a standby might fail to remove some WAL files that could be removed.
- Fix handling of commit-timestamp tracking during recovery (Masahiko Sawada, Michael Paquier)
  If commit timestamp tracking has been turned on or off, recovery might fail due to trying to fetch the commit timestamp for a transaction that did not record it.
- Randomize the `random()` seed in bootstrap and standalone backends, and in `initdb` (Noah Misch)
  The main practical effect of this change is that it avoids a scenario where `initdb` might mistakenly conclude that POSIX shared memory is not available, due to name collisions caused by always using the same random seed.
- Allow DSM allocation to be interrupted (Chris Travers)
- Properly handle turning `full_page_writes` on dynamically (Kyotaro Horiguchi)
- Avoid possible buffer overrun when replaying GIN page recompression from WAL (Alexander Korotkov, Sivasubramanian Ramasubramanian)
- Fix missed `fsync` of a replication slot’s directory (Konstantin Knizhnik, Michael Paquier)
- Fix unexpected timeouts when using `wal_sender_timeout` on a slow server (Noah Misch)
- Ensure that hot standby processes use the correct WAL consistency point (Alexander Kukushkin, Michael Paquier)
  This prevents possible misbehavior just after a standby server has reached a consistent database state during WAL replay.
- Ensure background workers are stopped properly when the postmaster receives a fast-shutdown request before completing database startup (Alexander Kukushkin)
- Don’t run atexit callbacks when servicing `SIGQUIT` (Heikki Linnakangas)
- Don’t record foreign-server user mappings as members of extensions (Tom Lane)
If `CREATE USER MAPPING` is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can't be extension members, so user mappings shouldn't be either.

- Make `syslogger` more robust against failures in opening CSV log files (Tom Lane)
- Fix `psql`, as well as documentation examples, to call `PQconsumeInput()` before each `PQnotifies()` call (Tom Lane)
  
  This fixes cases in which `psql` would not report receipt of a `NOTIFY` message until after the next command.
- Fix possible inconsistency in `pg_dump`'s sorting of dissimilar object names (Jacob Champion)
- Ensure that `pg_restore` will schema-qualify the table name when emitting `DISABLE/ENABLE TRIGGER` commands (Tom Lane)
  
  This avoids failures due to the new policy of running restores with restrictive search path.
- Fix `pg_upgrade` to handle event triggers in extensions correctly (Haribabu Kommi)
  
  `pg_upgrade` failed to preserve an event trigger's extension-membership status.
- Fix `pg_upgrade`'s cluster state check to work correctly on a standby server (Bruce Momjian)
- Enforce type `cube`'s dimension limit in all `contrib/cube` functions (Andrey Borodin)
  
  Previously, some cube-related functions could construct values that would be rejected by `cube_in()`, leading to dump/reload failures.
- Fix `contrib/unaccent`'s `unaccent()` function to use the `unaccent` text search dictionary that is in the same schema as the function (Tom Lane)
  
  Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.
- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)
  
  Adjust configure to add an `-isysroot` switch to `CPPFLAGS`; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific sysroot used can be overridden at configure time or build time by setting the `PG_SYSROOT` variable in the arguments of configure or make.
  
  It is now recommended that Perl-related extensions write `$perl_includespec` rather than `-I$(perl_archlibexp)/CORE` in their compiler flags. The latter continues to work on most platforms, but not recent macOS.
  
  Also, it should no longer be necessary to specify `--with-tclconfig` manually to get PL/Tcl to build on recent macOS releases.
- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)
  
  Perl no longer includes the current directory in its search path by default; work around that.
- On Windows, allow the regression tests to be run by an Administrator account (Andrew Dunstan)
  
  To do this safely, `pg_regress` now gives up any such privileges at startup.
- Support building on Windows with Visual Studio 2015 or Visual Studio 2017 (Michael Paquier, Haribabu Kommi)
- Allow `btree` comparison functions to return `INT_MIN` (Tom Lane)
Appendix E. Release Notes

Up to now, we’ve forbidden datatype-specific comparison functions from returning INT_MIN, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of memcmp(), strcmp(), etc, as POSIX doesn’t place any such restriction on those functions. At least some recent versions of memcmp() can return INT_MIN, causing incorrect sort ordering. Hence, we’ve removed this restriction. Callers must now use the INVERT_COMPARE_RESULT() macro if they wish to invert the sort order.

- Fix recursion hazard in shared-invalidation message processing (Tom Lane)
  This error could, for example, result in failure to access a system catalog or index that had just been processed by VACUUM FULL.

This change adds a new result code for LockAcquire, which might possibly affect external callers of that function, though only very unusual usage patterns would have an issue with it. The API of LockAcquireExtended is also changed.

- Save and restore SPI’s global variables during SPI_connect() and SPI_finish() (Chapman Flack, Tom Lane)
  This prevents possible interference when one SPI-using function calls another.

- Provide ALLOCSET_DEFAULT_SIZES and sibling macros in back branches (Tom Lane)
  These macros have existed since 9.6, but there were requests to add them to older branches to allow extensions to rely on them without branch-specific coding.

- Avoid using potentially-under-aligned page buffers (Tom Lane)
  Invent new union types PGAlignedBlock and PGAlignedXLogBlock, and use these in place of plain char arrays, ensuring that the compiler can’t place the buffer at a misaligned start address. This fixes potential core dumps on alignment-picky platforms, and may improve performance even on platforms that allow misalignment.

- Make src/port/snprintf.c follow the C99 standard’s definition of snprintf()’s result value (Tom Lane)
  On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to detect buffer overrun, if the calling code assumed C99 semantics.

- When building on i386 with the clang compiler, require -msse2 to be used (Andres Freund)
  This avoids problems with missed floating point overflow checks.

- Fix configure’s detection of the result type of strerror_r() (Tom Lane)
  The previous coding got the wrong answer when building withicc on Linux (and perhaps in other cases), leading to libpq not returning useful error messages for system-reported errors.

- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.

E.8. Release 9.5.14

Release date: 2018-08-09

2350
Appendix E. Release Notes

This release contains a variety of fixes from 9.5.13. For information about new features in the 9.5 major release, see Section E.22.

E.8.1. Migration to Version 9.5.14

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.13, see Section E.9.

E.8.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/.pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Fix INSERT ... ON CONFLICT UPDATE through a view that isn’t just SELECT * FROM ... (Dean Rasheed, Amit Langote)

Erroneous expansion of an updatable view could lead to crashes or “attribute ... has the wrong type” errors, if the view’s SELECT list doesn’t match one-to-one with the underlying table’s columns. Furthermore, this bug could be leveraged to allow updates of columns that an attacking user lacks UPDATE privilege for, if that user has INSERT and UPDATE privileges for some other column(s) of the table. Any user could also use it for disclosure of server memory. (CVE-2018-10925)

• Ensure that updates to the relfrozenxid and relminmxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Álvaro Herrera)

This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• During WAL replay, guard against corrupted record lengths exceeding 1GB (Michael Paquier)
Treat such a case as corrupt data. Previously, the code would try to allocate space and get a hard error, making recovery impossible.

- When ending recovery, delay writing the timeline history file as long as possible (Heikki Linnakangas)
  This avoids some situations where a failure during recovery cleanup (such as a problem with a two-phase state file) led to inconsistent timeline state on-disk.

- Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)
  This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.

- Improve performance of lock releasing in standby server WAL replay (Thomas Munro)

- Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)
  The code previously mis-detected whether or not it had caught up with the upstream server.

- Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)

- Ensure a table’s cached index list is correctly rebuilt after an index creation fails part way through (Peter Geoghegan)
  Previously, the failed index’s OID could remain in the list, causing problems later in the same session.

- Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)
  This could result in an assertion failure after pg_upgrade of a pre-9.4 GIN index (9.4 and later will not create such pages).

- Ensure that VACUUM will respond to signals within btree page deletion loops (Andres Freund)
  Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.

- Fix mis-optimization of equivalence classes involving composite-type columns (Tom Lane)
  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.

- Fix SQL-standard FETCH FIRST syntax to allow parameters ($n), as the standard expects (Andrew Gierth)

- Fix failure to schema-qualify some object names in getObjectDescription output (Kyotaro Horiguchi, Tom Lane)
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.

- Widen COPY FROM’s current-line-number counter from 32 to 64 bits (David Rowley)
  This avoids two problems with input exceeding 4G lines: COPY FROM WITH HEADER would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

- Add a string freeing function to ecpg’s pgtypes library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)
  On Windows, crashes can ensue if the free call for a given chunk of memory is not made from the same DLL that malloc’ed the memory. The pgtypes library sometimes returns strings that it expects
the caller to free, making it impossible to follow this rule. Add a `PGTYPESchar_free()` function that just wraps `free`, allowing applications to follow this rule.

- Fix `ecpg`'s support for `long long` variables on Windows, as well as other platforms that declare `strtoll`/`strtoull` nonstandardly or not at all (Dang Minh Huong, Tom Lane)

- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)

  This error led to assertion failures, or in rare cases, failure to enforce the `INTO STRICT` option as expected.

- Fix password prompting in client programs so that echo is properly disabled on Windows when `stdin` is not the terminal (Matthew Stickney)

- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)

  The previous fix for quoting of `search_path` and other list-valued variables in `pg_dump` output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Fix `pg_dump`'s failure to dump `REPLICA IDENTITY` properties for constraint indexes (Tom Lane)

  Manually created unique indexes were properly marked, but not those created by declaring `UNIQUE` or `PRIMARY KEY` constraints.

- Make `pg_upgrade` check that the old server was shut down cleanly (Bruce Momjian)

  The previous check could be fooled by an immediate-mode shutdown.

- Fix `contrib/hstore_plperl` to look through Perl scalar references, and to not crash if it doesn’t find a hash reference where it expects one (Tom Lane)

- Fix crash in `contrib/ltree`'s `lca()` function when the input array is empty (Pierre Ducroquet)

- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as `libpq.so`) rather than ones that might exist in the system library directories (Tom Lane)

  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to `tzdata` release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.

  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the `is_dst` column in the `pg_timezone_names` view will now be true in winter and false in summer in these cases.

---

**E.9. Release 9.5.13**

*Release date: 2018-05-10*
This release contains a variety of fixes from 9.5.12. For information about new features in the 9.5 major release, see Section E.22.

**E.9.1. Migration to Version 9.5.13**

A dump/restore is not required for those running 9.5.X.

However, if the function marking mistakes mentioned in the first changelog entry below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.5.12, see Section E.10.

**E.9.2. Changes**

- Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)
  The functions `query_to_xml`, `cursor_to_xml`, `cursor_to_xmlschema`, `query_to_xmlschema`, and `query_to_xml_and_xmlschema` should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ `pg_proc` entries, for example `ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE`. (Note that that will need to be done in each database of the installation.) Another option is to `pg_upgrade` the database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan Deolasee)
  Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors, which would persist until the dead entry was removed by `VACUUM`. Fix by not selecting such OIDs when creating a new TOAST entry.

- Change `ANALYZE`'s algorithm for updating `pg_class.reltuples` (David Gould)
  Previously, pages not actually scanned by `ANALYZE` were assumed to retain their old tuple density. In a large table where `ANALYZE` samples only a small fraction of the pages, this meant that the overall tuple density estimate could not change very much, so that `reltuples` would change nearly proportionally to changes in the table’s physical size (`retpages`) regardless of what was actually happening in the table. This has been observed to result in `reltuples` becoming so much larger than reality as to effectively shut off autovacuuming. To fix, assume that `ANALYZE`’s sample is a statistically unbiased sample of the table (as it should be), and just extrapolate the density observed within those pages to the whole table.

- Avoid deadlocks in concurrent `CREATE INDEX CONCURRENTLY` commands that are run under `SERIALIZABLE` or `REPEATABLE READ` transaction isolation (Tom Lane)

- Fix possible slow execution of `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Thomas Munro)
• Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an index-only-scan plan (Yugo Nagata, Tom Lane)

• Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)
  This error could result in misclassifying a condition as a “join filter” for an outer join when it should be a plain “filter” condition, leading to incorrect join output.

• Fix possibly incorrect generation of an index-only-scan plan when the same table column appears in multiple index columns, and only some of those index columns use operator classes that can return the column value (Kyotaro Horiguchi)

• Fix misoptimization of CHECK constraints having provably-NUL subclauses of top-level AND/OR conditions (Tom Lane, Dean Rasheed)
  This could, for example, allow constraint exclusion to exclude a child table that should not be excluded from a query.

• Fix executor crash due to double free in some GROUPING SET usages (Peter Geoghegan)

• Avoid crash if a table rewrite event trigger is added concurrently with a command that could call such a trigger (Álvaro Herrera, Andrew Gierth, Tom Lane)

• Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared transaction (Stas Kelvich)

• Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)

• Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)
  This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.

• Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)

• Reduce locking during autovacuum worker scheduling (Jeff Janes)
  The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.

• Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

• Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)

• Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
  Such searches would return the wrong set of rows in most non-C locales.

• Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

• Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

- Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)
- In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)
- Allow scalarltssel and scalargtssel to be used on non-core datatypes (Tomas Vondra)
- Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.
- Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)
- Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)
- Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)
  The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.
- Fix pg_recvlogical to not fail against pre-v10 PostgreSQL servers (Michael Paquier)
  A previous fix caused pg_recvlogical to issue a command regardless of server version, but it should only be issued to v10 and later servers.
- Ensure that pg_rewind deletes files on the target server if they are deleted from the source server during the run (Takayuki Tsunakawa)
  Failure to do this could result in data inconsistency on the target, particularly if the file in question is a WAL segment.
- Fix pg_rewind to handle tables in non-default tablespaces correctly (Takayuki Tsunakawa)
- Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)
  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.
- Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)
- Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)
- Support building with Microsoft Visual Studio 2015 (Michael Paquier)
  Various fixes needed for VS2015 compatibility were previously back-patched into the 9.5 branch, but this one was missed.
- Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)
- Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
Appendix E. Release Notes

This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

• Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.10. Release 9.5.12

Release date: 2018-03-01

This release contains a variety of fixes from 9.5.11. For information about new features in the 9.5 major release, see Section E.22.

E.10.1. Migration to Version 9.5.12

A dump/restore is not required for those running 9.5.X.

However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.5.10, see Section E.12.

E.10.2. Changes

• Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

Using a search_path setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.8.6 (for database administrators and users), Section 31.1 (for application authors), Section 35.15.1 (for extension authors), and CREATE FUNCTION (for authors of SECURITY DEFINER functions). (CVE-2018-1058)

• Avoid use of insecure search_path settings in pg_dump and other client programs (Noah Misch, Tom Lane)

pg_dump, pg_upgrade, vacuumdb and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are
commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)
  If a CTE (WITH clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)
  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair pg_upgrade’s failure to preserve `relfrozenxid` for materialized views (Tom Lane, Andres Freund)
  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before relfrozenxid” errors. The problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.
  If such corruption is observed, it can be repaired by refreshing the materialized view (without CONCURRENTLY).

- Fix incorrect reporting of PL/Python function names in error CONTEXT stacks (Tom Lane)
  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python DO block could result in a null pointer dereference crash on some platforms.

- Allow contrib/auto_explain’s `log_min_duration` setting to range up to `INT_MAX`, or about 24 days instead of 35 minutes (Tom Lane)

### E.11. Release 9.5.11

**Release date:** 2018-02-08

This release contains a variety of fixes from 9.5.10. For information about new features in the 9.5 major release, see Section E.22.

#### E.11.1. Migration to Version 9.5.11

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.10, see Section E.12.
E.11.2. Changes

- Ensure that all temporary files made by pg_upgrade are non-world-readable (Tom Lane, Noah Misch)
  pg_upgrade normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user’s `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using pg_upgrade in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)
  In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)
  These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Fix incorrect query results from cases involving flattening of subqueries whose outputs are used in `GROUPING SETS` (Heikki Linnakangas)

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by `ALTER TABLE NO INHERIT` (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running `CREATE INDEX CONCURRENTLY` (Jeff Janes)

- Fix failures when an inheritance tree contains foreign child tables (Etsuro Fujita)
  A mix of regular and foreign tables in an inheritance tree resulted in creation of incorrect plans for `UPDATE` and `DELETE` queries. This led to visible failures in some cases, notably when there are row-level triggers on a foreign child table.

- Repair failure with correlated sub-`SELECT` inside `VALUES` inside a `LATERAL` subquery (Tom Lane)

- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested `UNION ALL` inside a lateral subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)
  Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix `has_sequence_privilege()` to support `WITH GRANT OPTION` tests, as other privilege-testing functions do (Joe Conway)

- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)
  We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-
Appendix E. Release Notes

ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only `xpath()` and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)
  
  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)
  
  Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of `fork()` failure or other low-probability problems.

- Avoid unsafe alignment assumptions when working with `__int128` (Tom Lane)
  
  Typically, compilers assume that `__int128` variables are aligned on 16-byte boundaries, but our memory allocation infrastructure isn’t prepared to guarantee that, and increasing the setting of MAXALIGN seems infeasible for multiple reasons. Adjust the code to allow use of `__int128` only when we can tell the compiler to assume lesser alignment. The only known symptom of this problem so far is crashes in some parallel aggregation queries.

- Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)

- Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)

- Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)
  
  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.

  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.

- Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)

  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.

  Note that this change has user-visible results in the output of `pg_restore --list`.

- Rename `pg_rewind`’s `copy_file_range` function to avoid conflict with new Linux system call of that name (Andres Freund)

  This change prevents build failures with newer glibc versions.
Appendix E. Release Notes

- In ecpg, detect indicator arrays that do not have the correct length and report an error (David Rader)
- Avoid triggering a libc assertion in contrib/hstore, due to use of memcpy() with equal source and destination pointers (Tomas Vondra)
- Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
  The scripts in contrib/start-scripts/osx use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.
- Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)
- Support linking to MinGW-built versions of libperl (Noah Misch)
  This allows building PL/Perl with some common Perl distributions for Windows.
- Fix MSVC build to test whether 32-bit libperl needs -D_USE_32BIT_TIME_T (Noah Misch)
  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.
- On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.
- On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)
- Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)
- Add support for spinlocks on Motorola 88K (David Carlier)
- Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.12. Release 9.5.10

Release date: 2017-11-09

This release contains a variety of fixes from 9.5.9. For information about new features in the 9.5 major release, see Section E.22.

E.12.1. Migration to Version 9.5.10

A dump/restore is not required for those running 9.5.X.
However, if you use BRIN indexes, see the fourth changelog entry below.
Also, if you are upgrading from a version earlier than 9.5.8, see Section E.14.
E.12.2. Changes

- Ensure that `INSERT ... ON CONFLICT DO UPDATE` checks table permissions and RLS policies in all cases (Dean Rasheed)

  The update path of `INSERT ... ON CONFLICT DO UPDATE` requires `SELECT` permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updated rows against the table’s `SELECT` policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in `json{b}_populate_recordset()` (Michael Paquier, Tom Lane)

  These functions used the result rowtype specified in the `FROM ... AS` clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become `$PGUSER` before opening `$PGLOG` (Noah Misch)

  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making `$PGLOG` be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing `$PGLOG` file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)

  Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)

  These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

- Fix `json_build_array()`, `json_build_object()`, and their `jsonb` equivalents to handle explicit `VARIADIC` arguments correctly (Michael Paquier)

- Properly reject attempts to convert infinite float values to type `numeric` (Tom Lane, KaiGai Kohei)

  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains `FieldSelect` or `FieldStore` expression nodes (Tom Lane)

  Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Correctly ignore RelabelType expression nodes when determining relation distinctness (David Rowley)
  This allows the intended optimization to occur when a subquery has a result column of type `varchar`.
- Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.
- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)
- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)
- Allow COPY’s FREEZE option to work when the transaction isolation level is REPEATABLE READ or higher (Noah Misch)
  This case was unintentionally broken by a previous bug fix.
- Correctly restore the umask setting when file creation fails in COPY or lo_export() (Peter Eisentraut)
- Give a better error message for duplicate column names in ANALYZE (Nathan Bossart)
- Fix mis-parsing of the last line in a non-newline-terminated pg_hba.conf file (Tom Lane)
- Fix pg_basebackup’s matching of tablespace paths to canonicalize both paths before comparing (Michael Paquier)
  This is particularly helpful on Windows.
- Fix libpq to not require user’s home directory to exist (Tom Lane)
  In v10, failure to find the home directory while trying to read `~/.pgpass` was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading `~/.pg_service.conf`, though this was less obvious since that file is not sought unless a service name is specified.
- Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)
- Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
- In ecpglib, correctly handle backslashes in string literals depending on whether `standard_conforming_strings` is set (Tsunakawa Takayuki)
- Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
- Fix missing temp-install prerequisites for check-like Make targets (Noah Misch)
  Some non-default test procedures that are meant to work like make check failed to ensure that the temporary installation was up to date.
- Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
Appendix E. Release Notes

This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no `posixrules` file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.

- Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.13. Release 9.5.9

Release date: 2017-08-31

This release contains a small number of fixes from 9.5.8. For information about new features in the 9.5 major release, see Section E.22.

E.13.1. Migration to Version 9.5.9

A dump/restore is not required for those running 9.5.X.

However, if you are upgrading from a version earlier than 9.5.8, see Section E.14.

E.13.2. Changes

- Show foreign tables in `information_schema.table_privileges` view (Peter Eisentraut)

  All other relevant `information_schema` views include foreign tables, but this one ignored them.

  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:

  ```sql
  SET search_path TO information_schema;
  CREATE OR REPLACE VIEW table_privileges AS
  SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
         CAST(grantee.rolname AS sql_identifier) AS grantee,
         CAST(current_database() AS sql_identifier) AS table_catalog,
         CAST(nc.nspname AS sql_identifier) AS table_schema,
         CAST(c.relname AS sql_identifier) AS table_name,
         CAST(c.prtype AS character_data) AS privilege_type,
         CAST(
           CASE WHEN
             -- object owner always has grant options
             pg_has_role(grantee.oid, c.relowner, 'USAGE')
             OR c.grantable
             THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
         CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
  FROM (  
    SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class
    ) c
  ```

  Note: The above SQL code is for illustrative purposes only and may not work as-is in your environment.

  To fix this, you can use the following SQL command inside psql:

  ```sql
  SET search_path TO information_schema;
  CREATE OR REPLACE VIEW table_privileges AS
  ```

  This will update the view definition to include foreign tables and fix the problem in the existing installation.
Appendix E. Release Notes

) AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, pg_namespace nc, pg_authid u_grantor,
) AS grantee (oid, rolname)

WHERE c.relnamespace = nc.oid
AND c.relkind IN ('r', 'v', 'f')
AND c.grantee = grantee.oid
AND c.grantor = u_grantor.oid
AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
AND (pg_has_role(u_grantor.oid, 'USAGE')
OR pg_has_role(grantee.oid, 'USAGE')
OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
  
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.

- Remove assertion that could trigger during a fatal exit (Tom Lane)

- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)

  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.

- Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrizio de Royes Mello)

- Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)

  This allows ecpg programs to contain SQL constructs that use RETURNING internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)

  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of time_t values. A side-effect that may be visible to extension developers is that _USE_32BIT_TIME_T is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type time_t is not used in any PostgreSQL API definitions.

- Fix make check to behave correctly when invoked via a non-GNU make program (Thomas Munro)
Appendix E. Release Notes

E.14. Release 9.5.8

Release date: 2017-08-10

This release contains a variety of fixes from 9.5.7. For information about new features in the 9.5 major release, see Section E.22.

E.14.1. Migration to Version 9.5.8

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.7, see Section E.15.

E.14.2. Changes

• Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)

The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself.

Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you’ll still need a restart.)

2. In each database of the cluster, run the following commands as superuser:

   ```sql
   SET search_path = pg_catalog;
   CREATE OR REPLACE VIEW pg_user_mappings AS
   SELECT
       U.oid AS umid,
       S.oid AS srvid,
       S.srvname AS srvname,
       U.umuser AS umuser,
       CASE WHEN U.umuser = 0 THEN 'public'
       ELSE A.rolname END AS usename,
       CASE WHEN U.umuser <> 0 AND A.rolname = current_user
             AND (pg_has_role(S.srvowner, 'USAGE')
                OR has_server_privilege(S.oid, 'USAGE'))
   ```
Appendix E. Release Notes

OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user)
THEN U.umoptions
ELSE NULL END AS umoptions
FROM pg_user_mapping U
LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
pg_foreign_server S ON (U.umserver = S.oid);

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
and then after fixing template0, undo that with
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
In prior versions, instead use
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

• Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

• Make lo_put() check for UPDATE privilege on the target large object (Tom Lane, Michael Paquier)
lo_put() should surely require the same permissions as lowrite(), but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

• Correct the documentation about the process for upgrading standby servers with pg_upgrade (Bruce Momjjan)
The previous documentation instructed users to start/stop the primary server after running pg_upgrade but before syncing the standby servers. This sequence is unsafe.

• Fix concurrent locking of tuple update chains (Álvaro Herrera)
If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and conclude there is no live tuple version) due to a race condition. This had consequences such as foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.

• Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one still-interesting member (Teodor Sigaev)
Appendix E. Release Notes

- Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory (Sergey Koposov)

- On Windows, retry process creation if we fail to reserve the address range for our shared memory in the new process (Tom Lane, Amit Kapila)
  
  This is expected to fix infrequent child-process-launch failures that are probably due to interference from antivirus products.

- Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas Munro, Tom Lane)

- Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael Paquier)

- Prevent sending SSL session tickets to clients (Tom Lane)
  
  This fix prevents reconnection failures with ticket-aware client-side SSL code.

- Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)

- Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and immediate restart (Tom Lane)
  
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively ignored.

- Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size is less than that.

- Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes an XLOG_SWITCH WAL record (Andres Freund)

- Fix walsender to exit promptly when client requests shutdown (Tom Lane)

- Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)

- Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael Paquier)

- Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom Lane)

- Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  
  This resulted in temporary files consuming excessive disk space.

- Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Freund, Petr Jelinek)
  
  The previous algorithm was infeasibly expensive on a server with a lot of open transactions.

- Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund, Petr Jelinek)

- Reduce overhead in processing syscache invalidation events (Tom Lane)
  
  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

- Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of domain-over-array type (Tom Lane)
Appendix E. Release Notes

- Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate function (Tom Lane)

- Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE; this fix extends that behavior to renaming operations.

- Fix dangling pointer in ALTER TABLE when there is a comment on a constraint belonging to the table (David Rowley)
  Re-applying the comment to the reconstructed constraint could fail with a weird error message, or even crash.

- Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET does (Peter Eisentraut)

- Properly update dependency info when changing a datatype I/O function’s argument or return type from opaque to the correct type (Heikki Linnakangas)
  CREATE TYPE updates I/O functions declared in this long-obscure style, but it forgot to record a dependency on the type, allowing a subsequent DROP TYPE to leave broken function definitions behind.

- Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)

- Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by integers or floats (Tom Lane)

- Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte characters as whitespace.

- Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

- In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)
  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

- In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)
  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

- Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)
  This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

- Improve pg_dump/pg_restore’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)

- Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)
Appendix E. Release Notes

It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

- Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)
- Fix pg_dump output to stdout on Windows (Kuntal Ghosh)
  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.
- Fix `pg_get_ruledef()` to print correct output for the `ON SELECT` rule of a view whose columns have been renamed (Tom Lane)
  In some corner cases, pg_dump relies on `pg_get_ruledef()` to dump views, so that this error could result in dump/reload failures.
- Fix dumping of outer joins with empty constraints, such as the result of a `NATURAL LEFT JOIN` with no common columns (Tom Lane)
- Fix dumping of function expressions in the `FROM` clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)
- Fix `pg_basebackup` output to stdout on Windows (Haribabu Kommi)
  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.
- Fix `pg_rewind` to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)
  Ordinarily such files won’t appear in PostgreSQL data directories, but they could be present in some cases.
- Fix `pg_upgrade` to ensure that the ending WAL record does not have `wal_level = minimum` (Bruce Momjian)
  This condition could prevent upgraded standby servers from reconnecting.
- Fix `pg_xlogdump`’s computation of WAL record length (Andres Freund)
- In `postgres_fdw`, re-establish connections to remote servers after `ALTER SERVER` or `ALTER USER MAPPING` commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.
- In `postgres_fdw`, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.
- Increase `MAX_SYSCACHE_CALLBACKS` to provide more room for extensions (Tom Lane)
- Always use `-fpic`, not `-fpic`, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
- Fix unescaped-braces issue in our build scripts for Microsoft MSVC, to avoid a warning or error from recent Perl versions (Andrew Dunstan)
- In MSVC builds, handle the case where the openssl library is not within a `VC` subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
This fixes a former need to move things around in standard Windows installations of libxml2.

- In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)
- In MSVC builds, honor PROVE_FLAGS settings on vcregress.pl’s command line (Andrew Dunstan)

E.15. Release 9.5.7

Release date: 2017-05-11

This release contains a variety of fixes from 9.5.6. For information about new features in the 9.5 major release, see Section E.22.

E.15.1. Migration to Version 9.5.7

A dump/restore is not required for those running 9.5.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.

Also, if you are upgrading from a version earlier than 9.5.6, see Section E.16.

E.15.2. Changes

- Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)

  The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.14.

- Prevent exposure of statistical information via leaky operators (Peter Eisentraut)

  Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to
Appendix E. Release Notes

read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)
  Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its document-
  ation remained. This creates a security hazard, since users might be relying on the environment variable to
  force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, 
  but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)
  The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could
  cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was
  more likely to happen if the source server was busy at the time of slot creation, or if another logical slot
  already existed.

  If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at
  the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against
  the source server.

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)
  This could result in an unlogged index being set to an invalid state after a crash and restart. Such a
  problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but
  uncommitted two-phase transaction (Tom Lane)
  In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular
  references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified
  by the two-phase transaction.

• Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

• Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)

• Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)
  Previously, the postmaster updated portions of its state as though the process had been launched suc-
  cessfully, resulting in subsequent confusion.

• Fix crash or wrong answers when a GROUPING SETS column’s data type is hashable but not sortable
  (Pavan Deolasee)

• Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)
  This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for
  ordinary Postgres tuples; but it might not be the case for a custom scan provider.

• Use the correct sub-expression when applying a FOR ALL row-level-security policy (Stephen Frost)
  In some cases the WITH CHECK restriction would be applied when the USING restriction is more appro-
  priate.

• Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien
  Rouhaud, Tom Lane)
Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as `ALTER TABLE ... RENAME`.

- **Skip tablespace privilege checks when `ALTER TABLE ... ALTER COLUMN TYPE` rebuilds an existing index (Noah Misch)**
  
  The command failed if the calling user did not currently have `CREATE` privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.

- **Fix `ALTER TABLE ... VALIDATE CONSTRAINT` to not recurse to child tables when the constraint is marked `NO INHERIT` (Amit Langote)**
  
  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.

- **Avoid dangling pointer in `COPY ... TO` when row-level security is active for the source table (Tom Lane)**
  
  Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.

- **Avoid accessing an already-closed relcache entry in `CLUSTER` and `VACUUM FULL` (Tom Lane)**
  
  With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.

- **Fix `VACUUM` to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)**
  
  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, `VACUUM` could incorrectly report that the table contained no tuples, leading to very bad planning choices.

- **Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)**

- **Fix integer-overflow problems in `interval` comparison (Kyotaro Horiguchi, Tom Lane)**
  
  The comparison operators for type `interval` could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

- **Fix `cursor_to_xml()` to produce valid output with `tableforest = false` (Thomas Munro, Peter Eisentraut)**
  
  Previously it failed to produce a wrapping `<table>` element.

- **Fix roundoff problems in `float8_timestamptz()` and `make_interval()` (Tom Lane)**
  
  These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

- **Fix `pg_get_object_address()` to handle members of operator families correctly (Álvaro Herrera)**

- **Improve performance of `pg_timezone_names` view (Tom Lane, David Rowley)**

- **Reduce memory management overhead for contexts containing many large blocks (Tom Lane)**

- **Fix sloppy handling of corner-case errors from `lseek()` and `close()` (Tom Lane)**
Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.

- Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.
- Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)
- Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)
- In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.
- Avoid emitting an invalid list file in pg_restore -l when SQL object names contain newlines (Tom Lane)
  Replace newlines by spaces, which is sufficient to make the output valid for pg_restore -L’s purposes.
- Fix pg_upgrade to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.
- Improve error handling in contrib/adminpack’s pg_file_write() function (Noah Misch)
  Notably, it failed to detect errors reported by fclose().
- In contrib/dblink, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)
- Fix contrib/pg_trgm’s extraction of trigrams from regular expressions (Tom Lane)
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.
- In contrib/postgres_fdw, transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early. This is a back-patch of work originally done for 9.6.
- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)
- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  This fixes a bug affecting some DST transitions in January 2038.
- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.
Appendix E. Release Notes

The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.

• Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)
  The Microsoft MSVC build scripts neglected to install the posixrules file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October).
  With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the posixrules file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.

E.16. Release 9.5.6

Release date: 2017-02-09

This release contains a variety of fixes from 9.5.5. For information about new features in the 9.5 major release, see Section E.22.

E.16.1. Migration to Version 9.5.6

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.5.5, see Section E.17.

E.16.2. Changes

• Fix a race condition that could cause indexes built with CREATE INDEX CONCURRENTLY to be corrupt (Pavan Deolasee, Tom Lane)
  
  If CREATE INDEX CONCURRENTLY was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the CREATE INDEX command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

• Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning (Tom Lane)
Appendix E. Release Notes

Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- Fix incorrect WAL logging for BRIN indexes (Kuntal Ghosh)
  The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- Unconditionally WAL-log creation of the “init fork” for an unlogged table (Michael Paquier)
  Previously, this was skipped when wal_level = minimal, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)
  This change avoids substantial replication delays that sometimes occurred while replaying such operations.

- If the stats collector dies during hot standby, restart it (Takayuki Tsunakawa)

- Ensure that hot standby feedback works correctly when it’s enabled at standby server start (Ants Aasma, Craig Ringer)

- Check for interrupts while hot standby is waiting for a conflicting query (Simon Riggs)

- Avoid constantly respawning the autovacuum launcher in a corner case (Amit Khandekar)
  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- Fix check for when an extension member object can be dropped (Tom Lane)
  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

- Make sure ALTER TABLE preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
  Previously, non-default settings of default_tablespace could result in broken indexes.

- Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with ALTER TABLE . . . ALTER CONSTRAINT (Tom Lane)
  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

- Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

- Fix ALTER TABLE . . . SET DATA TYPE . . . USING when child table has different column ordering than the parent (Álvaro Herrera)
  Failure to adjust the column numbering in the USING expression led to errors, typically “attribute N has wrong type”.

- Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via ALTER TABLE . . . INHERIT (Amit Langote)
The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

- Fix `CREATE OR REPLACE VIEW` to update the view query before attempting to apply the new view options (Dean Rasheed)
  Previous the command would fail if the new options were inconsistent with the old view definition.

- Report correct object identity during `ALTER TEXT SEARCH CONFIGURATION` (Artur Zakirov)
  The wrong catalog OID was reported to extensions such as logical decoding.

- Fix commit timestamp mechanism to not fail when queried about the special XIDs `FrozenTransactionId` and `BootstrapTransactionId` (Craig Ringer)

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)
  When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Fix incorrect use of view rel options as regular table rel options (Tom Lane)
  The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of `INSERT ... ON CONFLICT` is a view with cascade option.

- Fix incorrect “target lists can have at most \( N \) entries” complaint when using `ON CONFLICT` with wide tables (Tom Lane)

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvectors` (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)

- Fix `ts_rewrite()`’s handling of nested NOT operators (Tom Lane)

- Improve speed of user-defined aggregates that use `array_append()` as transition function (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)
• Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)

• Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

• Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

• Disable transform that attempted to remove no-op AT TIME ZONE conversions (Tom Lane)
  This resulted in wrong answers when the simplified expression was used in an index condition.

• Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)
  In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from `INTERVAL MONTH` to `INTERVAL YEAR` failed to clear the months field.

• Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)

• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)

• Fix `pg_dump` to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

• Fix `pg_restore` with `--create --if-exists` to behave more sanely if an archive contains unrecognized DROP commands (Tom Lane)
  This doesn’t fix any live bug, but it may improve the behavior in future if `pg_restore` is used with an archive generated by a later `pg_dump` version.

• Fix `pg_basebackup`’s rate limiting in the presence of slow I/O (Antonin Houska)
  If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

• Fix `pg_basebackup`’s handling of symlinked `pg_stat_tmp` and `pg_replslot` subdirectories (Magnus Hagander, Michael Paquier)

• Fix possible `pg_basebackup` failure on standby server when including WAL files (Amit Kapila, Robert Haas)

• Fix possible mishandling of expanded arrays in domain check constraints and `CASE` execution (Tom Lane)
  It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

• Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)

• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
  This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

• Fix PL/Tcl to support triggers on tables that have `.tupno` as a column name (Tom Lane)
Appendix E. Release Notes

This matches the (previously undocumented) behavior of PL/Tcl’s `spi_exec` and `spi_execp` commands, namely that a magic `.tupno` column is inserted only if there isn’t a real column named that.

- Allow DOS-style line endings in `~/.pgpass` files, even on Unix (Vik Fearing)
  This change simplifies use of the same password file across Unix and Windows machines.
- Fix one-byte buffer overrun if `ecpg` is given a file name that ends with a dot (Takayuki Tsunakawa)
- Fix `psql`’s tab completion for `ALTER DEFAULT PRIVILEGES` (Gilles Darold, Stephen Frost)
- In `psql`, treat an empty or all-blank setting of the `PAGER` environment variable as meaning “no pager” (Tom Lane)
  Previously, such a setting caused output intended for the pager to vanish entirely.
- Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)
- Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)
  Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.
- Fix portability problems in contrib/pageinspect’s functions for GIN indexes (Peter Eisentraut, Tom Lane)
- On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
- Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)
  This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.
- Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.17. Release 9.5.5

Release date: 2016-10-27

This release contains a variety of fixes from 9.5.4. For information about new features in the 9.5 major release, see Section E.22.

E.17.1. Migration to Version 9.5.5

A dump/restore is not required for those running 9.5.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted free space maps.

Also, if you are upgrading from a version earlier than 9.5.2, see Section E.20.
E.17.2. Changes

- Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

  It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

  Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

- Fix incorrect creation of GIN index WAL records on big-endian machines (Tom Lane)

  The typical symptom was “unexpected GIN leaf action” errors during WAL replay.

- Fix SELECT FOR UPDATE/SHARE to correctly lock tuples that have been updated by a subsequently-aborted transaction (Álvaro Herrera)

  In 9.5 and later, the SELECT would sometimes fail to return such tuples at all. A failure has not been proven to occur in earlier releases, but might be possible with concurrent updates.

- Fix EvalPlanQual rechecks involving CTE scans (Tom Lane)

  The recheck would always see the CTE as returning no rows, typically leading to failure to update rows that were recently updated.

- Fix deletion of speculatively inserted TOAST tuples when backing out of INSERT ... ON CONFLICT (Oskari Saarenmaa)

  In the race condition where two transactions try to insert conflicting tuples at about the same time, the loser would fail with an “attempted to delete invisible tuple” error if its insertion included any TOAST'ed fields.

- Don’t throw serialization errors for self-conflicting insertions in INSERT ... ON CONFLICT (Thomas Munro, Peter Geoghegan)

- Fix improper repetition of previous results from hashed aggregation in a subquery (Andrew Gierth)

  The test to see if we can reuse a previously-computed hash table of the aggregate state values neglected the possibility of an outer query reference appearing in an aggregate argument expression. A change in the value of such a reference should lead to recalculating the hash table, but did not.

- Fix query-lifespan memory leak in a bulk UPDATE on a table with a PRIMARY KEY or REPLICA IDENTITY index (Tom Lane)

- Fix COPY with a column name list from a table that has row-level security enabled (Adam Brightwell)

- Fix EXPLAIN to emit valid XML when trackio_timing is on (Markus Winand)

  Previously the XML output-format option produced syntactically invalid tags such as <I/O-Read-Time>. That is now rendered as <I-O-Read-Time>.

- Suppress printing of zeroes for unmeasured times in EXPLAIN (Maksim Milyutin)
Certain option combinations resulted in printing zero values for times that actually aren’t ever measured in that combination. Our general policy in EXPLAIN is not to print such fields at all, so do that consistently in all cases.

- Fix statistics update for TRUNCATE in a prepared transaction (Stas Kelvich)
- Fix timeout length when VACUUM is waiting for exclusive table lock so that it can truncate the table (Simon Riggs)

  The timeout was meant to be 50 milliseconds, but it was actually only 50 microseconds, causing VACUUM to give up on truncation much more easily than intended. Set it to the intended value.
- Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)

  Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.
- Show a sensible value in pg_settings.unit for min_wal_size and max_wal_size (Tom Lane)
- Remove artificial restrictions on the values accepted by numeric_in() and numeric_recv() (Tom Lane)

  We allow numeric values up to the limit of the storage format (more than 1e100000), so it seems fairly pointless that numeric_in() rejected scientific-notation exponents above 1000. Likewise, it was silly for numeric_recv() to reject more than 1000 digits in an input value.
- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)

  With track_commit_timestamp turned on, old commit timestamps became inaccessible after a clean server restart.
- Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)
- Fix possible sorting error when aborting use of abbreviated keys (Peter Geoghegan)

  In the worst case, this could result in a corrupt btree index, which would need to be rebuilt using REINDEX. However, the situation is believed to be rare.
- Fix file descriptor leakage when truncating a temporary relation of more than 1GB (Andres Freund)
- Disallow starting a standalone backend with standby_mode turned on (Michael Paquier)

  This can’t do anything useful, since there will be no WAL receiver process to fetch more WAL data; and it could result in misbehavior in code that wasn’t designed with this situation in mind.
- Properly initialize replication slot state when recycling a previously-used slot (Michael Paquier)

  This failure to reset all of the fields of the slot could prevent VACUUM from removing dead tuples.
- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)

  This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.
• Use a more random value for the dynamic shared memory control segment’s ID (Robert Haas, Tom Lane)

Previously, the same value would be chosen every time, because it was derived from `random()` but `srandom()` had not yet been called. While relatively harmless, this was not the intended behavior.

• On Windows, retry creation of the dynamic shared memory control segment after an access-denied error (Kyotaro Horiguchi, Amit Kapila)

Windows sometimes returns `ERROR_ACCESS_DENIED` rather than `ERROR_ALREADY_EXISTS` when there is an existing segment. This led to postmaster startup failure due to believing that the former was an unrecoverable error.

• Fix PL/pgSQL to not misbehave with parameters and local variables of type `int2vector` or `oidvector` (Tom Lane)

• Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)

This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.

• Avoid corner-case memory leak in libpq (Tom Lane)

The reported problem involved leaking an error report during `PQreset()`, but there might be related cases.

• Make ecpg’s `--help` and `--version` options work consistently with our other executables (Haribabu Kommi)

• Fix pgbench’s calculation of average latency (Fabien Coelho)

The calculation was incorrect when there were `\sleep` commands in the script, or when the test duration was specified in number of transactions rather than total time.

• In pg_upgrade, check library loadability in name order (Tom Lane)

This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.

• In pg_dump, never dump range constructor functions (Tom Lane)

This oversight led to pg_upgrade failures with extensions containing range types, due to duplicate creation of the constructor functions.

• In pg_dump with `--C`, suppress `TABLESPACE` clause of `CREATE DATABASE` if `--no-tablespaces` is specified (Tom Lane)

• Make `pg_receivexlog` work correctly with `--synchronous` without slots (Gabriele Bartolini)

•Disallow specifying both `--source-server` and `--source-target` options to `pg_rewind` (Michael Banck)

• Make `pg_rewind` turn off `synchronous_commit` in its session on the source server (Michael Banck, Michael Paquier)

This allows `pg_rewind` to work even when the source server is using synchronous replication that is not working for some reason.

• In `pg_xlogdump`, retry opening new WAL segments when using `--follow` option (Magnus Hagander)

This allows for a possible delay in the server’s creation of the next segment.
Appendix E. Release Notes

- Fix pg_xlogdump to cope with a WAL file that begins with a continuation record spanning more than one page (Pavan Deolasee)
- Fix contrib/pg_buffercache to work when shared_buffers exceeds 256GB (KaiGai Kohei)
- Fix contrib/intarray/bench/bench.pl to print the results of the EXPLAIN it does when given the -e option (Daniel Gustafsson)
- Support OpenSSL 1.1.0 (Heikki Linnakangas)
- Install TAP test infrastructure so that it’s available for extension testing (Craig Ringer)
  When PostgreSQL has been configured with --enable-tap-tests, “make install” will now install the Perl support files for TAP testing where PGXS can find them. This allows non-core extensions to use $(prove_check) without extra tests.
- In MSVC builds, include pg_recvlogical in a client-only installation (MauMau)
- Update Windows time zone mapping to recognize some time zone names added in recent Windows versions (Michael Paquier)
- Prevent failure of obsolete dynamic time zone abbreviations (Tom Lane)
  If a dynamic time zone abbreviation does not match any entry in the referenced time zone, treat it as equivalent to the time zone name. This avoids unexpected failures when IANA removes abbreviations from their time zone database, as they did in tzdata release 2016f and seem likely to do again in the future. The consequences were not limited to not recognizing the individual abbreviation; any mismatch caused the pg_timezone_abbrevs view to fail altogether.
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.18. Release 9.5.4

Release date: 2016-08-11

This release contains a variety of fixes from 9.5.3. For information about new features in the 9.5 major release, see Section E.22.

E.18.1. Migration to Version 9.5.4

A dump/restore is not required for those running 9.5.X.
Appendix E. Release Notes

However, if you are upgrading from a version earlier than 9.5.2, see Section E.20.

E.18.2. Changes

• Fix possible mis-evaluation of nested CASE-WHEN expressions (Heikki Linnakangas, Michael Paquier, Tom Lane)

A CASE expression appearing within the test value subexpression of another CASE could become confused about whether its own test value was null or not. Also, inlining of a SQL function implementing the equality operator used by a CASE expression could result in passing the wrong test value to functions called within a CASE expression in the SQL function’s body. If the test values were of different data types, a crash might result; moreover such situations could be abused to allow disclosure of portions of server memory. (CVE-2016-5423)

• Fix client programs’ handling of special characters in database and role names (Noah Misch, Nathan Bossart, Michael Paquier)

Numerous places in vacuumdb and other client programs could become confused by database and role names containing double quotes or backslashes. Tighten up quoting rules to make that safe. Also, ensure that when a conninfo string is used as a database name parameter to these programs, it is correctly treated as such throughout.

Fix handling of paired double quotes in psql’s \connect and \password commands to match the documentation.

Introduce a new -reuse-previous option in psql’s \connect command to allow explicit control of whether to re-use connection parameters from a previous connection. (Without this, the choice is based on whether the database name looks like a conninfo string, as before.) This allows secure handling of database names containing special characters in pg_dumpall scripts.

pg_dumpall now refuses to deal with database and role names containing carriage returns or newlines, as it seems impractical to quote those characters safely on Windows. In future we may reject such names on the server side, but that step has not been taken yet.

These are considered security fixes because crafted object names containing special characters could have been used to execute commands with superuser privileges the next time a superuser executes pg_dumpall or other routine maintenance operations. (CVE-2016-5424)

• Fix corner-case misbehaviors for IS NULL/IS NOT NULL applied to nested composite values (Andrew Gierth, Tom Lane)

The SQL standard specifies that IS NULL should return TRUE for a row of all null values (thus ROW(NULL,NULL) IS NULL yields TRUE), but this is not meant to apply recursively (thus ROW(NULL, ROW(NULL,NULL)) IS NULL yields FALSE). The core executor got this right, but certain planner optimizations treated the test as recursive (thus producing TRUE in both cases), and contrib/postgres_fdw could produce remote queries that misbehaved similarly.

• Fix “unrecognized node type” error for INSERT ... ON CONFLICT within a recursive CTE (a WITH item) (Peter Geoghegan)

• Fix INSERT ... ON CONFLICT to successfully match index expressions or index predicates that are simplified during the planner’s expression preprocessing phase (Tom Lane)
Appendix E. Release Notes

- Correctly handle violations of exclusion constraints that apply to the target table of an `INSERT ... ON CONFLICT` command, but are not one of the selected arbiter indexes (Tom Lane)
  Such a case should raise a normal constraint-violation error, but it got into an infinite loop instead.
- Fix `INSERT ... ON CONFLICT` to not fail if the target table has a unique index on OID (Tom Lane)
- Make the `inet` and `cidr` data types properly reject IPv6 addresses with too many colon-separated fields (Tom Lane)
- Prevent crash in `close_ps()` (the `point ## lseg` operator) for NaN input coordinates (Tom Lane)
  Make it return NULL instead of crashing.
- Fix several one-byte buffer over-reads in `to_number()` (Peter Eisentraut)
  In several cases the `to_number()` function would read one more character than it should from the input string. There is a small chance of a crash, if the input happens to be adjacent to the end of memory.
- Do not run the planner on the query contained in `CREATE MATERIALIZED VIEW` or `CREATE TABLE AS` when `WITH NO DATA` is specified (Michael Paquier, Tom Lane)
  This avoids some unnecessary failure conditions, for example if a stable function invoked by the materialized view depends on a table that doesn’t exist yet.
- Avoid unsafe intermediate state during expensive paths through `heap_update()` (Masahiko Sawada, Andres Freund)
  Previously, these cases locked the target tuple (by setting its XMAX) but did not WAL-log that action, thus risking data integrity problems if the page were spilled to disk and then a database crash occurred before the tuple update could be completed.
- Fix hint bit update during WAL replay of row locking operations (Andres Freund)
  The only known consequence of this problem is that row locks held by a prepared, but uncommitted, transaction might fail to be enforced after a crash and restart.
- Avoid unnecessary “could not serialize access” errors when acquiring `FOR KEY SHARE` row locks in serializable mode (Álvaro Herrera)
- Make sure “expanded” datums returned by a plan node are read-only (Tom Lane)
  This avoids failures in some cases where the result of a lower plan node is referenced in multiple places in upper nodes. So far as core PostgreSQL is concerned, only array values returned by PL/pgSQL functions are at risk; but extensions might use expanded datums for other things.
- Avoid crash in `postgres -C` when the specified variable has a null string value (Michael Paquier)
- Prevent unintended waits for the receiver in WAL sender processes (Kyotaro Horiguchi)
- Fix possible loss of large subtransactions in logical decoding (Petru-Florin Mihancea)
- Fix failure of logical decoding when a subtransaction contains no actual changes (Marko Tiikkaja, Andrew Gierth)
- Ensure that backends see up-to-date statistics for shared catalogs (Tom Lane)
Appendix E. Release Notes

The statistics collector failed to update the statistics file for shared catalogs after a request from a regular backend. This problem was partially masked because the autovacuum launcher regularly makes requests that did cause such updates; however, it became obvious with autovacuum disabled.

- Avoid redundant writes of the statistics files when multiple backends request updates close together (Tom Lane, Tomas Vondra)
- Avoid consuming a transaction ID during VACUUM (Alexander Korotkov)
  Some cases in VACUUM unnecessarily caused an XID to be assigned to the current transaction. Normally this is negligible, but if one is up against the XID wraparound limit, consuming more XIDs during anti-wraparound vacuums is a very bad thing.
- Prevent possible failure when vacuuming multixact IDs in an installation that has been pg_upgrade’d from pre-9.3 (Andrew Gierth, Álvaro Herrera)
  The usual symptom of this bug is errors like “MultiXactId NNN has not been created yet -- apparent wraparound”.
- When a manual ANALYZE specifies a column list, don’t reset the table’s changes_since_analyze counter (Tom Lane)
  If we’re only analyzing some columns, we should not prevent routine auto-analyze from happening for the other columns.
- Fix ANALYZE’s overestimation of n_distinct for a unique or nearly-unique column with many null entries (Tom Lane)
  The nulls could get counted as though they were themselves distinct values, leading to serious planner misestimates in some types of queries.
- Prevent autovacuum from starting multiple workers for the same shared catalog (Álvaro Herrera)
  Normally this isn’t much of a problem because the vacuum doesn’t take long anyway; but in the case of a severely bloated catalog, it could result in all but one worker uselessly waiting instead of doing useful work on other tables.
- Fix bug in b-tree mark/restore processing (Kevin Grittner)
  This error could lead to incorrect join results or assertion failures in a merge join whose inner source node is a b-tree indexscan.
- Avoid duplicate buffer lock release when abandoning a b-tree index page deletion attempt (Tom Lane)
  This mistake prevented VACUUM from completing in some cases involving corrupt b-tree indexes.
- Fix building of large (bigger than shared_buffers) hash indexes (Tom Lane)
  The code path used for large indexes contained a bug causing incorrect hash values to be inserted into the index, so that subsequent index searches always failed, except for tuples inserted into the index after the initial build.
- Prevent infinite loop in GiST index build for geometric columns containing NaN component values (Tom Lane)
- Fix possible crash during a nearest-neighbor (ORDER BY distance) indexscan on a contrib/btree_gist index on an interval column (Peter Geoghegan)
- Fix “PANIC: failed to add BRIN tuple” error when attempting to update a BRIN index entry (Álvaro Herrera)
• Fix possible crash during background worker shutdown (Dmitry Ivanov)
• Fix PL/pgSQL’s handling of the INTO clause within IMPORT FOREIGN SCHEMA commands (Tom Lane)
• Fix contrib/btree_gin to handle the smallest possible bigint value correctly (Peter Eisentraut)
• Teach libpq to correctly decode server version from future servers (Peter Eisentraut)
  It’s planned to switch to two-part instead of three-part server version numbers for releases after 9.6.
  Make sure that PQserverVersion() returns the correct value for such cases.
• Fix ecpg’s code for unsigned long long array elements (Michael Meskes)
• In pg_dump with both -c and -C options, avoid emitting an unwanted CREATE SCHEMA public command (David Johnston, Tom Lane)
• Improve handling of SIGTERM/control-C in parallel pg_dump and pg_restore (Tom Lane)
  Make sure that the worker processes will exit promptly, and also arrange to send query-cancel requests to the connected backends, in case they are doing something long-running such as a CREATE INDEX.
• Fix error reporting in parallel pg_dump and pg_restore (Tom Lane)
  Previously, errors reported by pg_dump or pg_restore worker processes might never make it to the user’s console, because the messages went through the master process, and there were various deadlock scenarios that would prevent the master process from passing on the messages. Instead, just print everything to stderr. In some cases this will result in duplicate messages (for instance, if all the workers report a server shutdown), but that seems better than no message.
• Ensure that parallel pg_dump or pg_restore on Windows will shut down properly after an error (Kyotaro Horiguchi)
  Previously, it would report the error, but then just sit until manually stopped by the user.
• Make parallel pg_dump fail cleanly when run against a standby server (Magnus Hagander)
  This usage is not supported unless --no-synchronized-snapshots is specified, but the error was not handled very well.
• Make pg_dump behave better when built without zlib support (Kyotaro Horiguchi)
  It didn’t work right for parallel dumps, and emitted some rather pointless warnings in other cases.
• Make pg_basebackup accept -Z 0 as specifying no compression (Fujii Masao)
• Fix makefiles’ rule for building AIX shared libraries to be safe for parallel make (Noah Misch)
• Fix TAP tests and MSVC scripts to work when build directory’s path name contains spaces (Michael Paquier, Kyotaro Horiguchi)
• Be more predictable about reporting “statement timeout” versus “lock timeout” (Tom Lane)
  On heavily loaded machines, the regression tests sometimes failed due to reporting “lock timeout” even though the statement timeout should have occurred first.
• Make regression tests safe for Danish and Welsh locales (Jeff Janes, Tom Lane)
  Change some test data that triggered the unusual sorting rules of these locales.
• Update our copy of the timezone code to match IANA’s tzcode release 2016c (Tom Lane)
This is needed to cope with anticipated future changes in the time zone data files. It also fixes some corner-case bugs in coping with unusual time zones.

- Update time zone data files to tzdata release 2016f for DST law changes in Kemerovo and Novosibirsk, plus historical corrections for Azerbaijan, Belarus, and Morocco.

### E.19. Release 9.5.3

**Release date:** 2016-05-12

This release contains a variety of fixes from 9.5.2. For information about new features in the 9.5 major release, see Section E.22.

### E.19.1. Migration to Version 9.5.3

A dump/restore is not required for those running 9.5.X. However, if you are upgrading from a version earlier than 9.5.2, see Section E.20.

### E.19.2. Changes

- Clear the OpenSSL error queue before OpenSSL calls, rather than assuming it's clear already; and make sure we leave it clear afterwards (Peter Geoghegan, Dave Vitek, Peter Eisentraut)

  This change prevents problems when there are multiple connections using OpenSSL within a single process and not all the code involved follows the same rules for when to clear the error queue. Failures have been reported specifically when a client application uses SSL connections in libpq concurrently with SSL connections using the PHP, Python, or Ruby wrappers for OpenSSL. It’s possible for similar problems to arise within the server as well, if an extension module establishes an outgoing SSL connection.

- Fix “failed to build any $n$-way joins” planner error with a full join enclosed in the right-hand side of a left join (Tom Lane)

- Fix incorrect handling of equivalence-class tests in multilevel nestloop plans (Tom Lane)

  Given a three-or-more-way equivalence class of variables, such as \( X.X = Y.Y = Z.Z \), it was possible for the planner to omit some of the tests needed to enforce that all the variables are actually equal, leading to join rows being output that didn’t satisfy the \( \text{WHERE} \) clauses. For various reasons, erroneous plans were seldom selected in practice, so that this bug has gone undetected for a long time.

- Fix corner-case parser failures occurring when \texttt{operator_precedence_warning} is turned on (Tom Lane)

  An example is that \texttt{SELECT (ARRAY[]):text[]} gave an error, though it worked without the parentheses.

- Fix query-lifespan memory leak in GIN index scans (Julien Rouhaud)

- Fix query-lifespan memory leak and potential index corruption hazard in GIN index insertion (Tom Lane)
Appendix E. Release Notes

The memory leak would typically not amount to much in simple queries, but it could be very substantial during a large GIN index build with high `maintenance_work_mem`.

- Fix possible misbehavior of TH, th, and Y, YYY format codes in `to_timestamp()` (Tom Lane)
  These could advance off the end of the input string, causing subsequent format codes to read garbage.
- Fix dumping of rules and views in which the `array` argument of a `value` operator `ANY (array)` construct is a sub-SELECT (Tom Lane)
- Disallow newlines in `ALTER SYSTEM` parameter values (Tom Lane)
  The configuration-file parser doesn’t support embedded newlines in string literals, so we mustn’t allow them in values to be inserted by `ALTER SYSTEM`.
- Fix `ALTER TABLE ... REPLICA IDENTITY USING INDEX` to work properly if an index on OID is selected (David Rowley)
- Avoid possible misbehavior after failing to remove a tablespace symlink (Tom Lane)
- Fix crash in logical decoding on alignment-picky platforms (Tom Lane, Andres Freund)
  The failure occurred only with a transaction large enough to spill to disk and a primary-key change within that transaction.
- Avoid repeated requests for feedback from receiver while shutting down walsender (Nick Cleaton)
- Make `pg_regress` use a startup timeout from the `PGCTLTIMEOUT` environment variable, if that’s set (Tom Lane)
  This is for consistency with a behavior recently added to `pg_ctl`; it eases automated testing on slow machines.
- Fix `pg_upgrade` to correctly restore extension membership for operator families containing only one operator class (Tom Lane)
  In such a case, the operator family was restored into the new database, but it was no longer marked as part of the extension. This had no immediate ill effects, but would cause later `pg_dump` runs to emit output that would cause (harmless) errors on restore.
- Fix `pg_upgrade` to not fail when new-cluster TOAST rules differ from old (Tom Lane)
  `pg_upgrade` had special-case code to handle the situation where the new PostgreSQL version thinks that a table should have a TOAST table while the old version did not. That code was broken, so remove it, and instead do nothing in such cases; there seems no reason to believe that we can’t get along fine without a TOAST table if that was okay according to the old version’s rules.
- Fix atomic operations for PPC when using IBM’s XL compiler (Noah Misch)
- Reduce the number of SysV semaphores used by a build configured with `--disable-spinlocks` (Tom Lane)
- Rename internal function `strtoi()` to `strtoint()` to avoid conflict with a NetBSD library function (Thomas Munro)
- Fix reporting of errors from `bind()` and `listen()` system calls on Windows (Tom Lane)
- Reduce verbosity of compiler output when building with Microsoft Visual Studio (Christian Ullrich)
- Support building with Visual Studio 2015 (Michael Paquier, Petr Jelínek)
  Note that builds made with VS2015 will not run on Windows versions before Windows Vista.
Appendix E. Release Notes

- Fix `putenv()` to work properly with Visual Studio 2013 (Michael Paquier)
- Avoid possibly-unsafe use of Windows’ `FormatMessage()` function (Christian Ullrich)
  
  Use the `FORMAT_MESSAGE_IGNORE_INSERTS` flag where appropriate. No live bug is known to exist here, but it seems like a good idea to be careful.

- Update time zone data files to `tzdata` release 2016d for DST law changes in Russia and Venezuela. There are new zone names `Europe/Kirov` and `Asia/Tomsk` to reflect the fact that these regions now have different time zone histories from adjacent regions.

E.20. Release 9.5.2

Release date: 2016-03-31

This release contains a variety of fixes from 9.5.1. For information about new features in the 9.5 major release, see Section E.22.

E.20.1. Migration to Version 9.5.2

A dump/restore is not required for those running 9.5.X.

However, you may need to `REINDEX` some indexes after applying the update, as per the first changelog entry below.

E.20.2. Changes

- Disable abbreviated keys for string sorting in non-`C` locales (Robert Haas)
  
  PostgreSQL 9.5 introduced logic for speeding up comparisons of string data types by using the standard C library function `strxfrm()` as a substitute for `strcoll()`. It now emerges that most versions of glibc (Linux’s implementation of the C library) have buggy implementations of `strxfrm()` that, in some locales, can produce string comparison results that do not match `strcoll()`. Until this problem can be better characterized, disable the optimization in all non-`C` locales. (C locale is safe since it uses neither `strcoll()` nor `strxfrm()`.)

  Unfortunately, this problem affects not only sorting but also entry ordering in B-tree indexes, which means that B-tree indexes on `text`, `varchar`, or `char` columns may now be corrupt if they sort according to an affected locale and were built or modified under PostgreSQL 9.5.0 or 9.5.1. Users should `REINDEX` indexes that might be affected.

  It is not possible at this time to give an exhaustive list of known-affected locales. C locale is known safe, and there is no evidence of trouble in English-based locales such as `en_US`, but some other popular locales such as `de_DE` are affected in most glibc versions.

- Maintain row-security status properly in cached plans (Stephen Frost)
In a session that performs queries as more than one role, the plan cache might incorrectly re-use a plan that was generated for another role ID, thus possibly applying the wrong set of policies when row-level security (RLS) is in use. (CVE-2016-2193)

- Add must-be-superuser checks to some new contrib/pageinspect functions (Andreas Seltenreich)
  Most functions in the pageinspect extension that inspect bytea values disallow calls by non-superusers, but brin_page_type() and brin_metapage_info() failed to do so. Passing contrived bytea values to them might crash the server or disclose a few bytes of server memory. Add the missing permissions checks to prevent misuse. (CVE-2016-3065)

- Fix incorrect handling of indexed ROW() comparisons (Simon Riggs)
  Flaws in a minor optimization introduced in 9.5 caused incorrect results if the ROW() comparison matches the index ordering partially but not exactly (for example, differing column order, or the index contains both ASC and DESC columns). Pending a better solution, the optimization has been removed.

- Fix incorrect handling of NULL index entries in indexed ROW() comparisons (Tom Lane)
  An index search using a row comparison such as ROW(a, b) > ROW(‘x’, ‘y’) would stop upon reaching a NULL entry in the b column, ignoring the fact that there might be non-NUL b values associated with later values of a.

- Avoid unlikely data-loss scenarios due to renaming files without adequate fsync() calls before and after (Michael Paquier, Tomas Vondra, Andres Freund)

- Fix incorrect behavior when rechecking a just-modified row in a query that does SELECT FOR UPDATE/SHARE and contains some relations that need not be locked (Tom Lane)
  Rows from non-locked relations were incorrectly treated as containing all NULLs during the recheck, which could result in incorrectly deciding that the updated row no longer passes the WHERE condition, or in incorrectly outputting NULLs.

- Fix bug in json_to_record() when a field of its input object contains a sub-object with a field name matching one of the requested output column names (Tom Lane)

- Fix nonsense result from two-argument form of jsonb_object() when called with empty arrays (Michael Paquier, Andrew Dunstan)

- Fix misbehavior in jsonb_set() when converting a path array element into an integer for use as an array subscript (Michael Paquier)

- Fix misformatting of negative time zone offsets by to_char()’s OF format code (Thomas Munro, Tom Lane)

- Fix possible incorrect logging of waits done by INSERT ... ON CONFLICT (Peter Geoghegan)
  Log messages would sometimes claim that the wait was due to an exclusion constraint although no such constraint was responsible.

- Ignore recovery_min_apply_delay parameter until recovery has reached a consistent state (Michael Paquier)
  Previously, standby servers would delay application of WAL records in response to recovery_min_apply_delay even while replaying the initial portion of WAL needed to make their database state valid. Since the standby is useless until it’s reached a consistent database state, this was deemed unhelpful.
• Correctly handle cases where `pg_subtrans` is close to XID wraparound during server startup (Jeff Janes)
• Fix assorted bugs in logical decoding (Andres Freund)
  Trouble cases included tuples larger than one page when replica identity is `FULL`, `UPDATE` that change a primary key within a transaction large enough to be spooled to disk, incorrect reports of “subxact logged without previous toplevel record”, and incorrect reporting of a transaction’s commit time.
• Fix planner error with nested security barrier views when the outer view has a `WHERE` clause containing a correlated subquery (Dean Rasheed)
• Fix memory leak in GIN index searches (Tom Lane)
• Fix corner-case crash due to trying to free `localeconv()` output strings more than once (Tom Lane)
• Fix parsing of affix files for `ispell` dictionaries (Tom Lane)
  The code could go wrong if the affix file contained any characters whose byte length changes during case-folding, for example I in Turkish UTF8 locales.
• Avoid use of `sscanf()` to parse `ispell` dictionary files (Artur Zakirov)
  This dodges a portability problem on FreeBSD-derived platforms (including macOS).
• Fix atomic-operations code used on PPC with IBM’s xlc compiler (Noah Misch)
  This error led to rare failures of concurrent operations on that platform.
• Avoid a crash on old Windows versions (before 7SP1/2008R2SP1) with an AVX2-capable CPU and a PostgreSQL build done with Visual Studio 2013 (Christian Ullrich)
  This is a workaround for a bug in Visual Studio 2013’s runtime library, which Microsoft have stated they will not fix in that version.
• Fix `psql`'s tab completion logic to handle multibyte characters properly (Kyotaro Horiguchi, Robert Haas)
• Fix `psql`'s tab completion for `SECURITY LABEL` (Tom Lane)
  Pressing TAB after `SECURITY LABEL` might cause a crash or offering of inappropriate keywords.
• Make `pg_ctl` accept a wait timeout from the `PGCTLTIMEOUT` environment variable, if none is specified on the command line (Noah Misch)
  This eases testing of slower buildfarm members by allowing them to globally specify a longer-than-normal timeout for postmaster startup and shutdown.
• Fix incorrect test for Windows service status in `pg_ctl` (Manuel Mathar)
  The previous set of minor releases attempted to fix `pg_ctl` to properly determine whether to send log messages to Window’s Event Log, but got the test backwards.
• Fix pgbench to correctly handle the combination of `-C` and `-M` prepared options (Tom Lane)
• In `pg_upgrade`, skip creating a deletion script when the new data directory is inside the old data directory (Bruce Momjian)
  Blind application of the script in such cases would result in loss of the new data directory.
• In PL/Perl, properly translate empty Postgres arrays into empty Perl arrays (Alex Hunsaker)
• Make PL/Python cope with function names that aren’t valid Python identifiers (Jim Nasby)
Appendix E. Release Notes

- Fix multiple mistakes in the statistics returned by contrib/pgstattuple's pgstatindex() function (Tom Lane)
- Remove dependency on psed in MSVC builds, since it’s no longer provided by core Perl (Michael Paquier, Andrew Dunstan)
- Update time zone data files to tzdata release 2016c for DST law changes in Azerbaijan, Chile, Haiti, Palestine, and Russia (Altai, Astrakhan, Kirov, Sakhalin, Ulyanovsk regions), plus historical corrections for Lithuania, Moldova, and Russia (Kaliningrad, Samara, Volgograd).

E.21. Release 9.5.1

Release date: 2016-02-11

This release contains a variety of fixes from 9.5.0. For information about new features in the 9.5 major release, see Section E.22.

E.21.1. Migration to Version 9.5.1

A dump/restore is not required for those running 9.5.X.

E.21.2. Changes

- Fix infinite loops and buffer-overrun problems in regular expressions (Tom Lane)
  
  Very large character ranges in bracket expressions could cause infinite loops in some cases, and memory overwrites in other cases. (CVE-2016-0773)

- Fix an oversight that caused hash joins to miss joining to some tuples of the inner relation in rare cases (Tomas Vondra, Tom Lane)

- Avoid pushdown of HAVING clauses when grouping sets are used (Andrew Gierth)

- Fix deparsing of ON CONFLICT arbiter WHERE clauses (Peter Geoghegan)

- Make %h and %r escapes in log_line_prefix work for messages emitted due to log_connections (Tom Lane)
  
  Previously, %h/%r started to work just after a new session had emitted the “connection received” log message; now they work for that message too.

- Avoid leaking a token handle during SSPI authentication (Christian Ullrich)

- Fix psql’s \det command to interpret its pattern argument the same way as other \d commands with potentially schema-qualified patterns do (Reece Hart)

- In pg_ctl on Windows, check service status to decide where to send output, rather than checking if standard output is a terminal (Michael Paquier)

- Fix assorted corner-case bugs in pg_dump’s processing of extension member objects (Tom Lane)
• Fix improper quoting of domain constraint names in pg_dump (Elvis Pranskevichus)
• Make pg_dump mark a view’s triggers as needing to be processed after its rule, to prevent possible failure during parallel pg_restore (Tom Lane)
• Install guards in pgbench against corner-case overflow conditions during evaluation of script-specified division or modulo operators (Fabien Coelho, Michael Paquier)
• Suppress useless warning message when pg_receivexlog connects to a pre-9.4 server (Marco Nenciarini)
• Avoid dump/reload problems when using both plpython2 and plpython3 (Tom Lane)
In principle, both versions of PL/Python can be used in the same database, though not in the same session (because the two versions of libpython cannot safely be used concurrently). However, pg_restore and pg_upgrade both do things that can fall foul of the same-session restriction. Work around that by changing the timing of the check.
• Fix PL/Python regression tests to pass with Python 3.5 (Peter Eisentraut)
• Prevent certain PL/Java parameters from being set by non-superusers (Noah Misch)
This change mitigates a PL/Java security bug (CVE-2016-0766), which was fixed in PL/Java by marking these parameters as superuser-only. To fix the security hazard for sites that update PostgreSQL more frequently than PL/Java, make the core code aware of them also.
• Fix ecpg-supplied header files to not contain comments continued from a preprocessor directive line onto the next line (Michael Meskes)
Such a comment is rejected by ecpg. It’s not yet clear whether ecpg itself should be changed.
• Fix hstore_to_json_loose()’s test for whether an hstore value can be converted to a JSON number (Tom Lane)
Previously this function could be fooled by non-alphanumeric trailing characters, leading to emitting syntactically-invalid JSON.
• In contrib/postgres_fdw, fix bugs triggered by use of tableoid in data-modifying commands (Etsuro Fujita, Robert Haas)
• Fix ill-advised restriction of NAMEDATALEN to be less than 256 (Robert Haas, Tom Lane)
• Improve reproducibility of build output by ensuring filenames are given to the linker in a fixed order (Christoph Berg)
This avoids possible bitwise differences in the produced executable files from one build to the next.
• Ensure that dynloader.h is included in the installed header files in MSVC builds (Bruce Momjian, Michael Paquier)
• Update time zone data files to tzdata release 2016a for DST law changes in Cayman Islands, Metlakatla, and Trans-Baikal Territory (Zabaykalsky Krai), plus historical corrections for Pakistan.

E.22. Release 9.5

Release date: 2016-01-07
E.22.1. Overview

Major enhancements in PostgreSQL 9.5 include:

- Allow `INSERT`s that would generate constraint conflicts to be turned into `UPDATE`s or ignored
- Add `GROUP BY` analysis features `GROUPING SETS, CUBE` and `ROLLUP`
- Add row-level security control
- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication
- Add Block Range Indexes (BRIN)
- Substantial performance improvements for sorting
- Substantial performance improvements for multi-CPU machines

The above items are explained in more detail in the sections below.

E.22.2. Migration to Version 9.5

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.5 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Adjust operator precedence to match the SQL standard (Tom Lane)
  
  The precedence of `<`, `>=` and `<>` has been reduced to match that of `<`, `>` and `. The precedence of `IS` tests (e.g., `x IS NULL`) has been reduced to be just below these six comparison operators. Also, multi-keyword operators beginning with `NOT` now have the precedence of their base operator (for example, `NOT BETWEEN` now has the same precedence as `BETWEEN`) whereas before they had inconsistent precedence, behaving like `NOT` with respect to their left operand but like their base operator with respect to their right operand. The new configuration parameter `operator_precedence_warning` can be enabled to warn about queries in which these precedence changes result in different parsing choices.

- Change `pg_ctl`’s default shutdown mode from `smart` to `fast` (Bruce Momjian)

  This means the default behavior will be to forcibly cancel existing database sessions, not simply wait for them to exit.

- Use assignment cast behavior for data type conversions in PL/pgSQL assignments, rather than converting to and from text (Tom Lane)

  This change causes conversions of Booleans to strings to produce `true` or `false`, not `t` or `f`. Other type conversions may succeed in more cases than before; for example, assigning a numeric value `3.9` to an integer variable will now assign `4` rather than failing. If no assignment-grade cast is defined for the particular source and destination types, PL/pgSQL will fall back to its old I/O conversion behavior.

- Allow characters in server command-line options to be escaped with a backslash (Andres Freund)

  Formerly, spaces in the options string always separated options, so there was no way to include a space in an option value. Including a backslash in an option value now requires writing `\\`.  

2395
Appendix E. Release Notes

- Change the default value of the GSSAPI `include_realm` parameter to 1, so that by default the realm is not removed from a GSS or SSPI principal name (Stephen Frost)
- Replace configuration parameter `checkpoint_segments` with `min_wal_size` and `max_wal_size` (Heikki Linnakangas)
  If you previously adjusted `checkpoint_segments`, the following formula will give you an approximately equivalent setting:

  \[
  \text{max_wal_size} = (3 \times \text{checkpoint_segments}) \times 16\text{MB}
  \]

  Note that the default setting for `max_wal_size` is much higher than the default `checkpoint_segments` used to be, so adjusting it might no longer be necessary.
- Control the Linux OOM killer via new environment variables `PG_OOM_ADJUST_FILE` and `PG_OOM_ADJUST_VALUE`, instead of compile-time options `LINUX_OOM_SCORE_ADJ` and `LINUX_OOM_ADJ` (Gurjeet Singh)
- Decommission server configuration parameter `ssl_renegotiation_limit`, which was deprecated in earlier releases (Andres Freund)
  While SSL renegotiation is a good idea in theory, it has caused enough bugs to be considered a net negative in practice, and it is due to be removed from future versions of the relevant standards. We have therefore removed support for it from PostgreSQL. The `ssl_renegotiation_limit` parameter still exists, but cannot be set to anything but zero (disabled). It’s not documented anymore, either.
- Remove server configuration parameter `autocommit`, which was already deprecated and non-operational (Tom Lane)
- Remove the `pg_authid` catalog’s `rolcatupdate` field, as it had no usefulness (Adam Brightwell)
- The `pg_stat_replication` system view’s `sent` field is now NULL, not zero, when it has no valid value (Magnus Hagander)
- Allow `json` and `jsonb` array extraction operators to accept negative subscripts, which count from the end of JSON arrays (Peter Geoghegan, Andrew Dunstan)
  Previously, these operators returned NULL for negative subscripts.

E.22.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 9.5 and the previous major release.

E.22.3.1. Server

E.22.3.1.1. Indexes

- Add Block Range Indexes (BRIN) (Álvaro Herrera)
  BRIN indexes store only summary data (such as minimum and maximum values) for ranges of heap blocks. They are therefore very compact and cheap to update; but if the data is naturally clustered, they can still provide substantial speedup of searches.
• Allow queries to perform accurate distance filtering of bounding-box-indexed objects (polygons, circles) using GiST indexes (Alexander Korotkov, Heikki Linnakangas)

Previously, to exploit such an index a subquery had to be used to select a large number of rows ordered by bounding-box distance, and the result then had to be filtered further with a more accurate distance calculation.

• Allow GiST indexes to perform index-only scans (Anastasia Lubennikova, Heikki Linnakangas, Andreas Karlsson)

• Add configuration parameter gin_pending_list_limit to control the size of GIN pending lists (Fujii Masao)

This value can also be set on a per-index basis as an index storage parameter. Previously the pending-list size was controlled by work_mem, which was awkward because appropriate values for work_mem are often much too large for this purpose.

• Issue a warning during the creation of hash indexes because they are not crash-safe (Bruce Momjian)

E.22.3.1.2. General Performance

• Improve the speed of sorting of varchar, text, and numeric fields via “abbreviated” keys (Peter Geoghegan, Andrew Gierth, Robert Haas)

• Extend the infrastructure that allows sorting to be performed by inlined, non-SQL-callable comparison functions to cover CREATE INDEX, REINDEX, and CLUSTER (Peter Geoghegan)

• Improve performance of hash joins (Tomas Vondra, Robert Haas)

• Improve concurrency of shared buffer replacement (Robert Haas, Amit Kapila, Andres Freund)

• Reduce the number of page locks and pins during index scans (Kevin Grittner)

The primary benefit of this is to allow index vacuums to be blocked less often.

• Make per-backend tracking of buffer pins more memory-efficient (Andres Freund)

• Improve lock scalability (Andres Freund)

This particularly addresses scalability problems when running on systems with multiple CPU sockets.

• Allow the optimizer to remove unnecessary references to left-joined subqueries (David Rowley)

• Allow pushdown of query restrictions into subqueries with window functions, where appropriate (David Rowley)

• Allow a non-leakproof function to be pushed down into a security barrier view if the function does not receive any view output columns (Dean Rasheed)

• Teach the planner to use statistics obtained from an expression index on a boolean-returning function, when a matching function call appears in WHERE (Tom Lane)

• Make ANALYZE compute basic statistics (null fraction and average column width) even for columns whose data type lacks an equality function (Oleksandr Shulgin)

• Speed up CRC (cyclic redundancy check) computations and switch to CRC-32C (Abhijit Menon-Sen, Heikki Linnakangas)

• Improve bitmap index scan performance (Teodor Sigaev, Tom Lane)
Appendix E. Release Notes

- Speed up `CREATE INDEX` by avoiding unnecessary memory copies (Robert Haas)
- Increase the number of buffer mapping partitions (Amit Kapila, Andres Freund, Robert Haas)
  This improves performance for highly concurrent workloads.

E.22.3.1.3. Monitoring

- Add per-table autovacuum logging control via new `log_autovacuum_min_duration` storage parameter (Michael Paquier)
- Add new configuration parameter `cluster_name` (Thomas Munro)
  This string, typically set in `postgresql.conf`, allows clients to identify the cluster. This name also appears in the process title of all server processes, allowing for easier identification of processes belonging to the same cluster.
- Prevent non-superusers from changing `log_disconnections` on connection startup (Fujii Masao)

E.22.3.1.4. SSL

- Check “Subject Alternative Names” in SSL server certificates, if present (Alexey Klyukin)
  When they are present, this replaces checks against the certificate’s “Common Name”.
- Add system view `pg_stat_ssl` to report SSL connection information (Magnus Hagander)
- Add libpq functions to return SSL information in an implementation-independent way (Heikki Linnakangas)
  While `PQgetssl()` can still be used to call OpenSSL functions, it is now considered deprecated because future versions of libpq might support other SSL implementations. When possible, use the new functions `PQsslAttribute()`, `PQsslAttributeNames()`, and `PQsslInUse()` to obtain SSL information in an SSL-implementation-independent way.
- Make libpq honor any OpenSSL thread callbacks (Jan Urbanski)
  Previously they were overwritten.

E.22.3.1.5. Server Settings

- Replace configuration parameter `checkpoint_segments` with `min_wal_size` and `max_wal_size` (Heikki Linnakangas)
  This change allows the allocation of a large number of WAL files without keeping them after they are no longer needed. Therefore the default for `max_wal_size` has been set to 1GB, much larger than the old default for `checkpoint_segments`. Also note that standby servers perform restartpoints to try to limit their WAL space consumption to `max_wal_size`; previously they did not pay any attention to `checkpoint_segments`.
- Control the Linux OOM killer via new environment variables `PG_OOM_ADJUST_FILE` and `PG_OOM_ADJUST_VALUE` (Gurjeet Singh)
Appendix E. Release Notes

The previous OOM control infrastructure involved compile-time options `LINUX_OOM_SCORE_ADJ` and `LINUX_OOM_ADJ`, which are no longer supported. The new behavior is available in all builds.

- Allow recording of transaction commit time stamps when configuration parameter `track_commit_timestamp` is enabled (Álvaro Herrera, Petr Jelínek)
  
  Time stamp information can be accessed using functions `pg_xact_commit_timestamp()` and `pg_last_committed_xact()`.

- Allow `local_preload_libraries` to be set by `ALTER ROLE SET` (Peter Eisentraut, Kyotaro Horiguchi)

- Allow autovacuum workers to respond to configuration parameter changes during a run (Michael Paquier)

- Make configuration parameter `debug_assertions` read-only (Andres Freund)
  
  This means that assertions can no longer be turned off if they were enabled at compile time, allowing for more efficient code optimization. This change also removes the `postgres -A` option.

- Allow setting `effective_ioConcurrency` on systems where it has no effect (Peter Eisentraut)

- Add system view `pg_file_settings` to show the contents of the server’s configuration files (Sawada Masahiko)

- Add `pending_restart` to the system view `pg_settings` to indicate a change has been made but will not take effect until a database restart (Peter Eisentraut)

- Allow `ALTER SYSTEM` values to be reset with `ALTER SYSTEM RESET` (Vik Fearing)
  
  This command removes the specified setting from `postgresql.auto.conf`.

E.22.3.2. Replication and Recovery

- Create mechanisms for tracking the progress of replication, including methods for identifying the origin of individual changes during logical replication (Andres Freund)
  
  This is helpful when implementing replication solutions.

- Rework truncation of the multixact commit log to be properly WAL-logged (Andres Freund)
  
  This makes things substantially simpler and more robust.

- Add `recovery.conf` parameter `recovery_target_action` to control post-recovery activity (Petr Jelínek)
  
  This replaces the old parameter `pause_at_recovery_target`.

- Add new `archive_mode` value `always` to allow standbys to always archive received WAL files (Fujii Masao)

- Add configuration parameter `wal_retrieve_retry_interval` to control WAL read retry after failure (Alexey Vasiliev, Michael Paquier)
  
  This is particularly helpful for warm standbys.

- Allow compression of full-page images stored in WAL (Rahila Syed, Michael Paquier)
This feature reduces WAL volume, at the cost of more CPU time spent on WAL logging and WAL replay. It is controlled by a new configuration parameter wal_compression, which currently is off by default.

- Archive WAL files with suffix .partial during standby promotion (Heikki Linnakangas)
- Add configuration parameter log_replication_commands to log replication commands (Fujii Masao)

  By default, replication commands, e.g. IDENTIFY_SYSTEM, are not logged, even when log_statement is set to all.

- Report the processes holding replication slots in pg_replication_slots (Craig Ringer)
  The new output column is active_pid.
- Allow recovery.conf’s primary_conninfo setting to use connection URIs, e.g. postgres:// (Alexander Shulgin)

### E.22.3.3. Queries

- Allow INSERTs that would generate constraint conflicts to be turned into UPDATEs or ignored (Peter Geoghegan, Heikki Linnakangas, Andres Freund)

  The syntax is INSERT ... ON CONFLICT DO NOTHING/UPDATE. This is the Postgres implementation of the popular UPSERT command.
- Add GROUP BY analysis features GROUPING SETS, CUBE and ROLLUP (Andrew Gierth, Atri Sharma)
- Allow setting multiple target columns in an UPDATE from the result of a single sub-SELECT (Tom Lane)

  This is accomplished using the syntax UPDATE tab SET (col1, col2, ...) = (SELECT ...).
- Add SELECT option SKIP LOCKED to skip locked rows (Thomas Munro)

  This does not throw an error for locked rows like NOWAIT does.
- Add SELECT option TABLESAMPLE to return a subset of a table (Petr Jelínek)

  This feature supports the SQL-standard table sampling methods. In addition, there are provisions for user-defined table sampling methods.
- Suggest possible matches for mistyped column names (Peter Geoghegan, Robert Haas)

### E.22.3.4. Utility Commands

- Add more details about sort ordering in EXPLAIN output (Marius Timmer, Lukas Kreft, Arne Scheffer)

  Details include COLLATE, DESC, USING, and NULLS FIRST/LAST.
- Make VACUUM log the number of pages skipped due to pins (Jim Nasby)
- Make TRUNCATE properly update the pg_stat* tuple counters (Alexander Shulgin)
Appendix E. Release Notes

E.22.3.4.1. REINDEX

- Allow `REINDEX` to reindex an entire schema using the `SCHEMA` option (Sawada Masahiko)
- Add `VERBOSE` option to `REINDEX` (Sawada Masahiko)
- Prevent `REINDEX DATABASE` and `SCHEMA` from outputting object names, unless `VERBOSE` is used (Simon Riggs)
- Remove obsolete `FORCE` option from `REINDEX` (Fujii Masao)

E.22.3.5. Object Manipulation

- Add row-level security control (Craig Ringer, KaiGai Kohei, Adam Brightwell, Dean Rasheed, Stephen Frost)
  This feature allows row-by-row control over which users can add, modify, or even see rows in a table. This is controlled by new commands `CREATE/ALTER/DROP POLICY` and `ALTER TABLE ... ENABLE/DISABLE ROW SECURITY`.
- Allow changing of the WAL logging status of a table after creation with `ALTER TABLE ... SET LOGGED / UNLOGGED` (Fabrízio de Royes Mello)
- Add `IF NOT EXISTS` clause to `CREATE TABLE AS`, `CREATE INDEX`, `CREATE SEQUENCE`, and `CREATE MATERIALIZED VIEW` (Fabrízio de Royes Mello)
- Add support for `IF EXISTS` to `ALTER TABLE ... RENAME CONSTRAINT` (Bruce Momjian)
- Allow some DDL commands to accept `CURRENT_USER` or `SESSION_USER`, meaning the current user or session user, in place of a specific user name (Kyotaro Horiguchi, Álvaro Herrera)
  This feature is now supported in `ALTER USER`, `ALTER GROUP`, `ALTER ROLE`, `GRANT`, and `ALTER object OWNER TO` commands.
- Support comments on domain constraints (Álvaro Herrera)
- Reduce lock levels of some create and alter trigger and foreign key commands (Simon Riggs, Andreas Karlsson)
- Allow `LOCK TABLE ... ROW EXCLUSIVE MODE` for those with `INSERT` privileges on the target table (Stephen Frost)
  Previously this command required `UPDATE`, `DELETE`, or `TRUNCATE` privileges.
- Apply table and domain `CHECK` constraints in order by name (Tom Lane)
  The previous ordering was indeterminate.
- Allow `CREATE/ALTER DATABASE` to manipulate `datistemplate` and `datallowconn` (Vik Fearing)
  This allows these per-database settings to be changed without manually modifying the `pg_database` system catalog.
E.22.3.5.1. Foreign Tables

- Add support for IMPORT FOREIGN SCHEMA (Ronan Dunklau, Michael Paquier, Tom Lane)
  
  This command allows automatic creation of local foreign tables that match the structure of existing tables on a remote server.

- Allow CHECK constraints to be placed on foreign tables (Shigeru Hanada, Etsuro Fujita)
  
  Such constraints are assumed to be enforced on the remote server, and are not enforced locally. However, they are assumed to hold for purposes of query optimization, such as constraint exclusion.

- Allow foreign tables to participate in inheritance (Shigeru Hanada, Etsuro Fujita)
  
  To let this work naturally, foreign tables are now allowed to have check constraints marked as not valid, and to set storage and OID characteristics, even though these operations are effectively no-ops for a foreign table.

- Allow foreign data wrappers and custom scans to implement join pushdown (KaiGai Kohei)

E.22.3.5.2. Event Triggers

- Whenever a ddl_command_end event trigger is installed, capture details of DDL activity for it to inspect (Álvaro Herrera)
  
  This information is available through a set-returning function pg_event_trigger_ddl_commands(), or by inspection of C data structures if that function doesn’t provide enough detail.

- Allow event triggers on table rewrites caused by ALTER TABLE (Dimitri Fontaine)

- Add event trigger support for database-level COMMENT, SECURITY LABEL, and GRANT/REVOKE (Álvaro Herrera)

- Add columns to the output of pg_event_trigger_dropped_objects (Álvaro Herrera)
  
  This allows simpler processing of delete operations.

E.22.3.6. Data Types

- Allow the xml data type to accept empty or all-whitespace content values (Peter Eisentraut)
  
  This is required by the SQL/XML specification.

- Allow macaddr input using the format xxxx:xxxx:xxxx (Herwin Weststrate)

- Disallow non-SQL-standard syntax for interval with both precision and field specifications (Bruce Momjian)
  
  Per the standard, such type specifications should be written as, for example, INTERVAL MINUTE TO SECOND. PostgreSQL formerly allowed this to be written as INTERVAL(2) MINUTE TO SECOND, but it must now be written in the standard way.
Appendix E. Release Notes

• Add selectivity estimators for inet/cidr operators and improve estimators for text search functions (Emre Hasegeli, Tom Lane)
• Add data types regrole and regnamespace to simplify entering and pretty-printing the OID of a role or namespace (Kyotaro Horiguchi)

E.22.3.6.1. JSON

• Add jsonb functions jsonb_set() and jsonb_pretty() (Dmitry Dolgov, Andrew Dunstan, Petr Jelínek)
• Add jsonb generator functions to_jsonb(), jsonb_object(), jsonb_build_object(), jsonb_build_array(), jsonb_agg(), and jsonb_object_agg() (Andrew Dunstan)
  Equivalent functions already existed for type json.
• Reduce casting requirements to/from json and jsonb (Tom Lane)
• Allow text, text array, and integer values to be subtracted from jsonb documents (Dmitry Dolgov, Andrew Dunstan)
• Add jsonb || operator (Dmitry Dolgov, Andrew Dunstan)
• Add json_strip_nulls() and jsonb_strip_nulls() functions to remove JSON null values from documents (Andrew Dunstan)

E.22.3.7. Functions

• Add generate_series() for numeric values (Plato Malugin)
• Allow array_agg() and ARRAY() to take arrays as inputs (Ali Akbar, Tom Lane)
• Add functions array_position() and array_positions() to return subscripts of array values (Pavel Stehule)
• Add a point-to-polygon distance operator <-> (Alexander Korotkov)
• Allow multibyte characters as escapes in SIMILAR TO and SUBSTRING (Jeff Davis)
  Previously, only a single-byte character was allowed as an escape.
• Add a width_bucket() variant that supports any sortable data type and non-uniform bucket widths (Petr Jelínek)
• Add an optional missing_ok argument to pg_read_file() and related functions (Michael Paquier, Heikki Linnakangas)
• Allow => to specify named parameters in function calls (Pavel Stehule)
  Previously only := could be used. This requires removing the possibility for => to be a user-defined operator. Creation of user-defined => operators has been issuing warnings since PostgreSQL 9.0.
• Add POSIX-compliant rounding for platforms that use PostgreSQL-supplied rounding functions (Pedro Gimeno Fortea)
Appendix E. Release Notes

E.22.3.7.1. System Information Functions and Views

- Add function `pg_get_object_address()` to return OIDs that uniquely identify an object, and function `pg_identify_object_as_address()` to return object information based on OIDs (Álvaro Herrera)
- Loosen security checks for viewing queries in `pg_stat_activity`, executing `pg_cancel_backend()`, and executing `pg_terminate_backend()` (Stephen Frost)
  Previously, only the specific role owning the target session could perform these operations; now membership in that role is sufficient.
- Add `pg_stat_get_snapshot_timestamp()` to output the time stamp of the statistics snapshot (Matt Kelly)
  This represents the last time the snapshot file was written to the file system.
- Add `mxid_age()` to compute multi-xid age (Bruce Momjian)

E.22.3.7.2. Aggregates

- Add `min()`/`max()` aggregates for `inet/cidr` data types (Haribabu Kommi)
- Use 128-bit integers, where supported, as accumulators for some aggregate functions (Andreas Karlsson)

E.22.3.8. Server-Side Languages

- Improve support for composite types in PL/Python (Ed Behn, Ronan Dunklau)
  This allows PL/Python functions to return arrays of composite types.
- Reduce lossiness of PL/Python floating-point value conversions (Marko Kreen)
- Allow specification of conversion routines between SQL data types and data types of procedural languages (Peter Eisentraut)
  This change adds new commands `CREATE/DROP TRANSFORM`. This also adds optional transformations between the `hstore` and `ltree` types to/from PL/Perl and PL/Python.

E.22.3.8.1. PL/pgSQL Server-Side Language

- Improve PL/pgSQL array performance (Tom Lane)
- Add an `ASSERT` statement in PL/pgSQL (Pavel Stehule)
- Allow more PL/pgSQL keywords to be used as identifiers (Tom Lane)
E.22.3.9. Client Applications

- Move `pg_archivecleanup`, `pg_test_fsync`, `pg_test_timing`, and `pg_xlogdump` from `contrib` to `src/bin` (Peter Eisentraut)
  This should result in these programs being installed by default in most installations.
- Add `pg_rewind`, which allows re-synchronizing a master server after failback (Heikki Linnakangas)
- Allow `pg_receivexlog` to manage physical replication slots (Michael Paquier)
  This is controlled via new `--create-slot` and `--drop-slot` options.
- Allow `pg_receivexlog` to synchronously flush WAL to storage using new `--synchronous` option (Furuya Osamu, Fujii Masao)
  Without this, WAL files are fsync’ed only on close.
- Allow vacuumdb to vacuum in parallel using new `--jobs` option (Dilip Kumar)
- In vacuumdb, do not prompt for the same password repeatedly when multiple connections are necessary (Haribabu Kommi, Michael Paquier)
- Add `--verbose` option to reindexdb (Sawada Masahiko)
- Make `pg_basebackup` use a tablespace mapping file when using tar format, to support symbolic links
  and file paths of 100+ characters in length on MS Windows (Amit Kapila)
- Add `pg_xlogdump` option `--stats` to display summary statistics (Abhijit Menon-Sen)

E.22.3.9.1. psql

- Allow `psql` to produce AsciiDoc output (Szymon Guz)
- Add an `errors` mode that displays only failed commands to `psql`’s `ECHO` variable (Pavel Stehule)
  This behavior can also be selected with `psql`’s `-b` option.
- Provide separate column, header, and border linestyle control in `psql`’s unicode linestyle (Pavel Stehule)
  Single or double lines are supported; the default is `single`.
- Add new option `%l` in `psql`’s `PROMPT` variables to display the current multiline statement line number
  (Sawada Masahiko)
- Add \pset option `pager_min_lines` to control pager invocation (Andrew Dunstan)
- Improve `psql` line counting used when deciding to invoke the pager (Andrew Dunstan)
- `psql` now fails if the file specified by an `--output` or `--log-file` switch cannot be written (Tom
  Lane, Daniel Vérité)
  Previously, it effectively ignored the switch in such cases.
- Add `psql` tab completion when setting the `search_path` variable (Jeff Janes)
  Currently only the first schema can be tab-completed.
- Improve `psql`’s tab completion for triggers and rules (Andreas Karlsson)
Appendix E. Release Notes

E.22.3.9.1.1. Backslash Commands

- Add psql `\?` help sections variables and options (Pavel Stehule)
  `\?` variables shows psql’s special variables and `\?` options shows the command-line options. `\? commands` shows the meta-commands, which is the traditional output and remains the default. These help displays can also be obtained with the command-line option `--help=section`.
- Show tablespace size in psql’s `\db+` (Fabrízio de Royes Mello)
- Show data type owners in psql’s `\dT+` (Magnus Hagander)
- Allow psql’s `\watch` to output `\timing` information (Fujii Masao)
  Also prevent `--echo-hidden` from echoing `\watch` queries, since that is generally unwanted.
- Make psql’s `\sf` and `\ef` commands honor ECHO_HIDDEN (Andrew Dunstan)
- Improve psql tab completion for `\set`, `\unset`, and `:variable` names (Pavel Stehule)
- Allow tab completion of role names in psql `\c` commands (Ian Barwick)

E.22.3.9.2. pg_dump

- Allow pg_dump to share a snapshot taken by another session using `--snapshot` (Simon Riggs, Michael Paquier)
  The remote snapshot must have been exported by `pg_export_snapshot()` or logical replication slot creation. This can be used to share a consistent snapshot across multiple pg_dump processes.
- Support table sizes exceeding 8GB in tar archive format (Tom Lane)
  The POSIX standard for tar format does not allow elements of a tar archive to exceed 8GB, but most modern implementations of tar support an extension that does allow it. Use the extension format when necessary, rather than failing.
- Make pg_dump always print the server and pg_dump versions (Jing Wang)
  Previously, version information was only printed in `--verbose` mode.
- Remove the long-ignored `-i/--ignore-version` option from pg_dump, pg_dumpall, and pg_restore (Fujii Masao)

E.22.3.9.3. pg_ctl

- Support multiple pg_ctl `-o` options, concatenating their values (Bruce Momjian)
- Allow control of pg_ctl’s event source logging on MS Windows (MauMau)
  This only controls pg_ctl, not the server, which has separate settings in `postgresql.conf`.
- If the server’s listen address is set to a wildcard value (0.0.0.0 in IPv4 or :: in IPv6), connect via the loopback address rather than trying to use the wildcard address literally (Kondo Yuta)
  This fix primarily affects Windows, since on other platforms pg_ctl will prefer to use a Unix-domain socket.
E.22.3.9.4. pg_upgrade

- Move pg_upgrade from contrib to src/bin (Peter Eisentraut)
  In connection with this change, the functionality previously provided by the pg_upgrade_support module has been moved into the core server.
- Support multiple pg_upgrade -o/-O options, concatenating their values (Bruce Momjian)
- Improve database collation comparisons in pg_upgrade (Heikki Linnakangas)
- Remove support for upgrading from 8.3 clusters (Bruce Momjian)

E.22.3.9.5. pgbench

- Move pgbench from contrib to src/bin (Peter Eisentraut)
- Fix calculation of TPS number “excluding connections establishing” (Tatsuo Ishii, Fabien Coelho)
  The overhead for connection establishment was miscalculated whenever the number of pgbench threads was less than the number of client connections. Although this is clearly a bug, we won’t back-patch it into pre-9.5 branches since it makes TPS numbers not comparable to previous results.
- Allow counting of pgbench transactions that take over a specified amount of time (Fabien Coelho)
  This is controlled by a new \-latency-limit option.
- Allow pgbench to generate Gaussian/exponential distributions using \setrandom (Kondo Mitsumasa, Fabien Coelho)
- Allow pgbench’s \set command to handle arithmetic expressions containing more than one operator, and add % (modulo) to the set of operators it supports (Robert Haas, Fabien Coelho)

E.22.3.10. Source Code

- Simplify WAL record format (Heikki Linnakangas)
  This allows external tools to more easily track what blocks are modified.
- Improve the representation of transaction commit and abort WAL records (Andres Freund)
- Add atomic memory operations API (Andres Freund)
- Allow custom path and scan methods (KaiGai Kohei, Tom Lane)
  This allows extensions greater control over the optimizer and executor.
- Allow foreign data wrappers to do post-filter locking (Etsuro Fujita)
- Foreign tables can now take part in\texttt{INSERT \ldots ON CONFLICT DO NOTHING} queries (Peter Geoghegan, Heikki Linnakangas, Andres Freund)
  Foreign data wrappers must be modified to handle this. \texttt{INSERT \ldots ON CONFLICT DO UPDATE} is not supported on foreign tables.
Appendix E. Release Notes

- Improve `hash_create()`'s API for selecting simple-binary-key hash functions (Teodor Sigaev, Tom Lane)
- Improve parallel execution infrastructure (Robert Haas, Amit Kapila, Noah Misch, Rushabh Lathia, Jeevan Chalke)
- Remove Alpha (CPU) and Tru64 (OS) ports (Andres Freund)
- Remove swap-byte-based spinlock implementation for ARMv5 and earlier CPUs (Robert Haas)
  ARMv5's weak memory ordering made this locking implementation unsafe. Spinlock support is still possible on newer gcc implementations with atomics support.
- Generate an error when excessively long (100+ character) file paths are written to tar files (Peter Eisentraut)
  Tar does not support such overly-long paths.
- Change index operator class for columns `pg_seclabel.provider` and `pg_shseclabel.provider` to be `text_pattern_ops` (Tom Lane)
  This avoids possible problems with these indexes when different databases of a cluster have different default collations.
- Change the spinlock primitives to function as compiler barriers (Robert Haas)

E.22.3.10.1. MS Windows

- Allow higher-precision time stamp resolution on Windows 8, Windows Server 2012, and later Windows systems (Craig Ringer)
- Install shared libraries to `bin` in MS Windows (Peter Eisentraut, Michael Paquier)
- Install `src/test/modules` together with `contrib` on MSVC builds (Michael Paquier)
- Allow `configure`'s `--with-extra-version` option to be honored by the MSVC build (Michael Paquier)
- Pass `PGFILEDESC` into MSVC contrib builds (Michael Paquier)
- Add icons to all MSVC-built binaries and version information to all MS Windows binaries (Noah Misch)
  MinGW already had such icons.
- Add optional-argument support to the internal `getopt_long()` implementation (Michael Paquier, Andres Freund)
  This is used by the MSVC build.

E.22.3.11. Additional Modules

- Add statistics for minimum, maximum, mean, and standard deviation times to `pg_stat_statements` (Mitsumasa Kondo, Andrew Dunstan)
Appendix E. Release Notes

- Add pgcrypto function `pgp_armor_headers()` to extract PGP armor headers (Marko Tiikkaja, Heikki Linnakangas)

- Allow empty replacement strings in unaccent (Mohammad Alhashash)
  
  This is useful in languages where diacritic signs are represented as separate characters.

- Allow multicharacter source strings in unaccent (Tom Lane)
  
  This could be useful in languages where diacritic signs are represented as separate characters. It also allows more complex unaccent dictionaries.

- Add contrib modules `tsm_system_rows` and `tsm_system_time` to allow additional table sampling methods (Petr Jelinek)

- Add GIN index inspection functions to `pageinspect` (Heikki Linnakangas, Peter Geoghegan, Michael Paquier)

- Add information about buffer pins to `pg_buffercache` display (Andres Freund)

- Allow `pgstattuple` to report approximate answers with less overhead using `pgstattuple_approx()` (Abhijit Menon-Sen)

- Move `dummy_seclabel`, `test_shm_mq`, `test_parser`, and `worker_spi` from contrib to `src/test/modules` (Álvaro Herrera)

  These modules are only meant for server testing, so they do not need to be built or installed when packaging PostgreSQL.

E.23. Prior Releases

Release notes for prior release branches can be found at https://www.postgresql.org/docs/release/
Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in modules found in contrib. Appendix G covers utility programs.

When building from the source distribution, these components are not built automatically, unless you build the "world" target (see step 2). You can build and install all of them by running:

\texttt{make make install}

in the contrib directory of a configured source tree; or to build and install just one selected module, do the same in that module’s subdirectory. Many of the modules have regression tests, which can be executed by running:

\texttt{make check}

before installation or

\texttt{make installcheck}

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these modules are typically made available as a separate subpackage, such as postgresql-contrib.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. In PostgreSQL 9.1 and later, this is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

\texttt{CREATE EXTENSION module_name;}

This command must be run by a database superuser. This registers the new SQL objects in the current database only, so you need to run this command in each database that you want the module’s facilities to be available in. Alternatively, run it in database template1 so that the extension will be copied into subsequently-created databases by default.

Many modules allow you to install their objects in a schema of your choice. To do that, add \texttt{SCHEMA schema_name} to the CREATE EXTENSION command. By default, the objects will be placed in your current creation target schema, which in turn defaults to public.

If your database was brought forward by dump and reload from a pre-9.1 version of PostgreSQL, and you had been using the pre-9.1 version of the module in it, you should instead do

\texttt{CREATE EXTENSION module_name FROM unpackaged;
Appendix F. Additional Supplied Modules

This will update the pre-9.1 objects of the module into a proper extension object. Future updates to the module will be managed by ALTER EXTENSION. For more information about extension updates, see Section 35.15.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each module for details.

F.1. adminpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is restricted to superusers.

The functions shown in Table F-1 provide write access to files on the machine hosting the server. (See also the functions in Table 9-76, which provide read-only access.) Only files within the database cluster directory can be accessed, but either a relative or absolute path is allowable.

Table F-1. adminpack Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_catalog.pg_file_write(filename, data text, append boolean)</code></td>
<td>bigint</td>
<td>Write, or append to, a text file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_rename(oldname, newname text [, archivename text])</code></td>
<td>boolean</td>
<td>Rename a file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_unlink(filename)</code></td>
<td>bigint</td>
<td>Remove a file</td>
</tr>
<tr>
<td><code>pg_catalog.pg_logdir_ls()</code></td>
<td>setof record</td>
<td>List the log files in the log_directory directory</td>
</tr>
</tbody>
</table>

`pg_file_write` writes the specified `data` into the file named by `filename`. If `append` is false, the file must not already exist. If `append` is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_rename` renames a file. If `archivename` is omitted or NULL, it simply renames `oldname` to `newname` (which must not already exist). If `archivename` is provided, it first renames `newname` to `archivename` (which must not already exist), and then renames `oldname` to `newname`. In event of failure of the second rename step, it will try to rename `archivename` back to `newname` before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the log_directory directory. The `log_filename` parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

The functions shown in Table F-2 are deprecated and should not be used in new applications; instead
use those shown in Table 9-67 and Table 9-76. These functions are provided in `adminpack` only for compatibility with old versions of pgAdmin.

Table F-2. Deprecated `adminpack` Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pg_catalog.pg_file_read(filename text, offset bigint, nbytes bigint)</code></td>
<td>text</td>
<td>Alternate name for <code>pg_read_file()</code></td>
</tr>
<tr>
<td><code>pg_catalog.pg_file_length(filename text)</code></td>
<td>bigint</td>
<td>Same as size column returned by <code>pg_stat_file()</code></td>
</tr>
<tr>
<td><code>pg_catalog.pg_logfile_rotate()</code></td>
<td>integer</td>
<td>Alternate name for <code>pg_rotate_logfile()</code>, but note that it returns integer 0 or 1 rather than boolean</td>
</tr>
</tbody>
</table>

### F.2. auth_delay

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via `shared_preload_libraries` in `postgresql.conf`.

#### F.2.1. Configuration Parameters

`auth_delay.milliseconds(int)`

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```sql
# postgresql.conf
shared_preload_libraries = 'auth_delay'
auth_delay.milliseconds = '500'
```

#### F.2.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>
Appendix F. Additional Supplied Modules

F.3. auto_explain

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including auto_explain in session_preload_libraries or shared_preload_libraries in postgresql.conf. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.3.1. Configuration Parameters

There are several configuration parameters that control the behavior of auto_explain. Note that the default behavior is to do nothing, so you must set at least auto_explain.log_min_duration if you want any results.

**auto_explain.log_min_duration** (integer)

auto_explain.log_min_duration is the minimum statement execution time, in milliseconds, that will cause the statement’s plan to be logged. Setting this to zero logs all plans. Minus-one (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

**auto_explain.log_analyze** (boolean)

auto_explain.log_analyze causes EXPLAIN ANALYZE output, rather than just EXPLAIN output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

**auto_explain.log_buffers** (boolean)

auto_explain.log_buffers controls whether buffer usage statistics are printed when an execution plan is logged; it’s equivalent to the BUFFERS option of EXPLAIN. This parameter has no effect unless auto_explain.log_analyze is enabled. This parameter is off by default. Only superusers can change this setting.

**auto_explain.log_timing** (boolean)

auto_explain.log_timing controls whether per-node timing information is printed when an execution plan is logged; it’s equivalent to the TIMING option of EXPLAIN. The overhead of repeatedly
Appendix F. Additional Supplied Modules

reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless \texttt{auto\_explain.log\_analyze} is enabled. This parameter is on by default. Only superusers can change this setting.

\texttt{auto\_explain.log\_triggers (boolean)}

\texttt{auto\_explain.log\_triggers} causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless \texttt{auto\_explain.log\_analyze} is enabled. This parameter is off by default. Only superusers can change this setting.

\texttt{auto\_explain.log\_verbose (boolean)}

\texttt{auto\_explain.log\_verbose} controls whether verbose details are printed when an execution plan is logged; it’s equivalent to the \texttt{VERBOSE} option of \texttt{EXPLAIN}. This parameter is off by default. Only superusers can change this setting.

\texttt{auto\_explain.log\_format (enum)}

\texttt{auto\_explain.log\_format} selects the \texttt{EXPLAIN} output format to be used. The allowed values are \texttt{text}, \texttt{xml}, \texttt{json}, and \texttt{yaml}. The default is \texttt{text}. Only superusers can change this setting.

\texttt{auto\_explain.log\_nested\_statements (boolean)}

\texttt{auto\_explain.log\_nested\_statements} causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

In ordinary usage, these parameters are set in \texttt{postgresql.conf}, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```bash
# postgresql.conf
session_preload_libraries = 'auto_explain'
auto_explain.log_min_duration = '3s'
```

F.3.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
   FROM pg_class, pg_index
   WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 3.651 ms  plan:
Query Text: SELECT count(*)
   FROM pg_class, pg_index
   WHERE oid = indrelid AND indisunique;
Aggregate (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1 loops=1)
   -> Hash Join (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92 loops=1)
      Hash Cond: (pg_class.oid = pg_index.indrelid)
```
Appendix F. Additional Supplied Modules

F.3.3. Author

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>

F.4. btree_gin

btree_gin provides sample GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, inet, and cidr.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

F.4.1. Example Usage

CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;

F.4.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.

F.5. btree_gist

btree_gist provides GiST index operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, numeric, timestamp with time zone, timestamp...
without time zone, time with time zone, date, interval, oid, money, char, varchar, text, bytea, bit, varbit, macaddr, inet, and cidr.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolonm GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an exclusion constraint, as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

### F.5.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```sql
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

=> CREATE TABLE zoo {
    cage INTEGER,
    animal TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
};

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR: conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL: Key (cage, animal)=(123, lion) conflicts with existing key (cage, animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```
Appendix F. Additional Supplied Modules

F.5.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), and Janko Richter (<jankorichter@yahoo.de>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information.

F.6. chkpass

This module implements a data type chkpass that is designed for storing encrypted passwords. Each password is automatically converted to encrypted form upon entry, and is always stored encrypted. To compare, simply compare against a clear text password and the comparison function will encrypt it before comparing.

There are provisions in the code to report an error if the password is determined to be easily crackable. However, this is currently just a stub that does nothing.

If you precede an input string with a colon, it is assumed to be an already-encrypted password, and is stored without further encryption. This allows entry of previously-encrypted passwords.

On output, a colon is prepended. This makes it possible to dump and reload passwords without re-encrypting them. If you want the encrypted password without the colon then use the raw() function. This allows you to use the type with things like Apache’s Auth_PostgreSQL module.

The encryption uses the standard Unix function crypt(), and so it suffers from all the usual limitations of that function; notably that only the first eight characters of a password are considered.

Note that the chkpass data type is not indexable.

Sample usage:

test=# create table test (p chkpass);
CREATE TABLE
test=# insert into test values ('hello');
INSERT 0 1
test=# select * from test;
P
--------------
:dVGkpXdOrE3ko
(1 row)

test=# select raw(p) from test;
raw
--------------
dVGkpXdOrE3ko
(1 row)

test=# select p = 'hello' from test;
?column?
----------
t
(1 row)
Appendix F. Additional Supplied Modules

---

test=# select p = 'goodbye' from test;
  ?column?
  ----------
  f
  (1 row)

F.6.1. Author
D’Arcy J.M. Cain (<darcy@druid.net>)

F.7. citext

The *citext* module provides a case-insensitive character string type, *citext*. Essentially, it internally calls *lower* when comparing values. Otherwise, it behaves almost exactly like *text*.

F.7.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the *lower* function when comparing values, for example:

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use *lower* on both the column and the query value.
- It won’t use an index, unless you create a functional index using *lower*.
- If you declare a column as *UNIQUE* or *PRIMARY KEY*, the implicitly generated index is case-sensitive. So it’s useless for case-insensitive searches, and it won’t enforce uniqueness case-insensitively.

The *citext* data type allows you to eliminate calls to *lower* in SQL queries, and allows a primary key to be case-insensitive. *citext* is locale-aware, just like *text*, which means that the matching of upper case and lower case characters is dependent on the rules of the database’s *LC_CTYPE* setting. Again, this behavior is identical to the use of *lower* in queries. But because it’s done transparently by the data type, you don’t have to remember to do anything special in your queries.

F.7.2. How to Use It

Here’s a simple example of usage:

```
CREATE TABLE users (  
  nick CITEXT PRIMARY KEY,  
  pass TEXT  NOT NULL
```

---

2418
SELECT * FROM users WHERE nick = 'Larry';

The SELECT statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

### F.7.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~~, and !~~ and !~~*. If you’d like to match case-sensitively, you can cast the operator’s arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

### F.7.4. Limitations

- citext’s case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms
Appendix F. Additional Supplied Modules

defined by the Unicode standard. Effectively, what this means is that, as long as you’re happy with your collation, you should be happy with citext’s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database’s LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.

- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. It is, however, slightly more efficient than using lower to get case-insensitive matching.

- citext doesn’t help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the text type and manually use the lower function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.

F.7.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original citext module by Donald Fraser.

F.8. cube

This module implements a data type cube for representing multidimensional cubes.

F.8.1. Syntax

Table F-3 shows the valid external representations for the cube type. x, y, etc. denote floating-point numbers.

<table>
<thead>
<tr>
<th>x</th>
<th>A one-dimensional point (or, zero-length one-dimensional interval)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x)</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

F.8. cube

This module implements a data type cube for representing multidimensional cubes.
A point in n-dimensional space, represented internally as a zero-volume cube

\((x_1, x_2, \ldots, x_n)\)

Same as above

\((x), (y)\)

A one-dimensional interval starting at \(x\) and ending at \(y\) or vice versa; the order does not matter

\([ (x), (y) ]\)

Same as above

\((x_1, \ldots, x_n), (y_1, \ldots, y_n)\)

An n-dimensional cube represented by a pair of its diagonally opposite corners

\([ [(x_1, \ldots, x_n), (y_1, \ldots, y_n)]\)

Same as above

It does not matter which order the opposite corners of a cube are entered in. The cube functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation.

White space is ignored, so \([ (x), (y) ]\) is the same as \([ (x), (y) ]\).

F.8.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.8.3. Usage

The cube module includes a GiST index operator class for cube values. The operators supported by the GiST operator class are shown in Table F-4.

Table F-4. Cube GiST Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a = b)</td>
<td>The cubes (a) and (b) are identical.</td>
</tr>
<tr>
<td>(a &amp; &amp; b)</td>
<td>The cubes (a) and (b) overlap.</td>
</tr>
<tr>
<td>(a @&gt; b)</td>
<td>The cube (a) contains the cube (b).</td>
</tr>
<tr>
<td>(a &lt;@ b)</td>
<td>The cube (a) is contained in the cube (b).</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators \(\@>\) and \(<\@\) were respectively called \(@\) and \(\sim\). These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>([a, b] &lt; [c, d])</td>
<td>Less than</td>
</tr>
<tr>
<td>([a, b] &gt; [c, d])</td>
<td>Greater than</td>
</tr>
</tbody>
</table>
These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

Table F-5 shows the available functions.

**Table F-5. Cube Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube(float8)</code> returns <code>cube</code></td>
<td>Makes a one dimensional cube with both coordinates the same. <code>cube(1) == '(1)’</code></td>
</tr>
<tr>
<td><code>cube(float8, float8)</code> returns <code>cube</code></td>
<td>Makes a one dimensional cube. <code>cube(1,2) == '(1),(2)'</code></td>
</tr>
<tr>
<td><code>cube(float8[])</code> returns <code>cube</code></td>
<td>Makes a zero-volume cube using the coordinates defined by the array. <code>cube(ARRAY[1,2]) == '(1,2)'</code></td>
</tr>
<tr>
<td><code>cube(float8[], float8[])</code> returns <code>cube</code></td>
<td>Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length. <code>cube('1,2':::float[], '3,4':::float[][]) == '(1,2),(3,4)'</code></td>
</tr>
<tr>
<td><code>cube(cube, float8)</code> returns <code>cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube with the same values for both parts of the new coordinate. This is useful for building cubes piece by piece from calculated values. <code>cube('(1)',2) == '(1,2),(1,2)'</code></td>
</tr>
<tr>
<td><code>cube(cube, float8, float8)</code> returns <code>cube</code></td>
<td>Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values. <code>cube('(1,2)',3,4) == '(1,3),(2,4)'</code></td>
</tr>
<tr>
<td><code>cube_dim(cube)</code> returns <code>int</code></td>
<td>Returns the number of dimensions of the cube</td>
</tr>
<tr>
<td><code>cube_ll_coord(cube, int)</code> returns <code>double</code></td>
<td>Returns the n'th coordinate value for the lower left corner of a cube</td>
</tr>
<tr>
<td><code>cube_ur_coord(cube, int)</code> returns <code>double</code></td>
<td>Returns the n'th coordinate value for the upper right corner of a cube</td>
</tr>
<tr>
<td><code>cube_is_point(cube)</code> returns <code>bool</code></td>
<td>Returns true if a cube is a point, that is, the two defining corners are the same.</td>
</tr>
<tr>
<td><code>cube_distance(cube, cube)</code> returns <code>double</code></td>
<td>Returns the distance between two cubes. If both cubes are points, this is the normal distance function.</td>
</tr>
</tbody>
</table>
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| `cube_subset(cube, int[]) returns cube` | Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to find both the LL and UR coordinates of a single dimension, e.g.  
  
  `cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[2]) = '(3),(7)'.` Or can be used to drop dimensions, or reorder them as desired, e.g.  
  
  `cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[3,2,1,1]) = '(5, 3, 1, 1),(8, 7, 6, 6)'.` |
| `cube_union(cube, cube) returns cube` | Produces the union of two cubes                                                                                                                                                                          |
| `cube_inter(cube, cube) returns cube` | Produces the intersection of two cubes                                                                                                                                                                   |
| `cube_enlarge(cube c, double r, int n) returns cube` | Increases the size of a cube by a specified radius in at least n dimensions. If the radius is negative the cube is shrunk instead. This is useful for creating bounding boxes around a point for searching for nearby points. All defined dimensions are changed by the radius r. LL coordinates are decreased by r and UR coordinates are increased by r. If a LL coordinate is increased to larger than the corresponding UR coordinate (this can only happen when r < 0) than both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being increased (r >= 0) then 0 is used as the base for the extra coordinates. |

#### F.8.4. Defaults

I believe this union:

```sql
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```sql
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-------------
(0, 0),(1, 0)
(1 row)
```
Appendix F. Additional Supplied Modules

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```sql
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```sql
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-------------
t
(1 row)
```

F.8.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.8.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.9. dblink

**dblink** is a module that supports connections to other PostgreSQL databases from within a database session.
See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

**dblink_connect**

**Name**

dblink_connect — opens a persistent connection to a remote database

**Synopsis**

dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text

**Description**

dblink_connect() establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper dblink_fdw when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

**Arguments**

**connname**

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

**connstr**

libpq-style connection info string, for example hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypassword options=-csearch_path=. For details see Section 31.1.1. Alternatively, the name of a foreign server.

**Return Value**

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).
Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to `connstr`. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
  dblink_connect
----------------
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work properly
--     Otherwise, you will receive the following error from dblink_connect():
--     ---------------------------------------------------------------
--     ERROR: password is required
--     DETAIL: Non-superuser cannot connect if the server does not request a password.
--     HINT: Target server’s authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname 'contrib_regression');
CREATE USER dblink_regression_test WITH PASSWORD 'secret';
CREATE USER MAPPING FOR dblink_regression_test SERVER fdtest OPTIONS (user 'dblink_regression_test', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO dblink_regression_test;
GRANT SELECT ON TABLE foo TO dblink_regression_test;

\set ORIGINAL_USER :USER
\c - dblink_regression_test
SELECT dblink_connect('myconn', 'fdtest');
  dblink_connect
----------------
OK
(1 row)

SELECT * FROM dblink('myconn','SELECT * FROM foo') AS t(a int, b text, c text[]);
  a | b | c
```

2426
REVOKE USAGE ON FOREIGN SERVER fdtest FROM dblink_regression_test;
REVOKE SELECT ON TABLE foo FROM dblink_regression_test;
DROP USER MAPPING FOR dblink_regression_test SERVER fdtest;
DROP USER dblink_regression_test;
DROP SERVER fdtest;
dblink_connect_u

Name

dblink_connect_u — opens a persistent connection to a remote database, insecurely

Synopsis

dblink_connect_u(text connstr) returns text
dblink_connect_u(text conname, text connstr) returns text

Description

dblink_connect_u() is identical to dblink_connect(), except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a ~/.pgpass file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, dblink_connect_u() is initially installed with all privileges revoked from PUBLIC, making it un-callable except by superusers. In some situations it may be appropriate to grant EXECUTE permission for dblink_connect_u() to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any ~/.pgpass file belonging to the server's user not contain any records specifying a wildcard host name.

For further details see dblink_connect().
dblink_disconnect

Name
dblink_disconnect — closes a persistent connection to a remote database

Synopsis
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text

Description
dblink_disconnect() closes a connection previously opened by dblink_connect(). The form with no arguments closes an unnamed connection.

Arguments
cconnname

The name of a named connection to be closed.

Return Value
Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Examples

SELECT dblink_disconnect();
dblink_disconnect
--------------------
   OK
(1 row)

SELECT dblink_disconnect('myconn');
dblink_disconnect
--------------------
   OK
(1 row)
dblink

Name
dblink — executes a query in a remote database

Synopsis
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record

Description
dblink executes a query (usually a SELECT, but it can be any SQL statement that returns rows) in a remote database.
When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

Arguments

connname
   Name of the connection to use; omit this parameter to use the unnamed connection.

connstr
   A connection info string, as previously described for dblink_connect.

sql
   The SQL query that you wish to execute in the remote database, for example select * from foo.

fail_on_error
   If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value
The function returns the row(s) produced by the query. Since dblink can be used with any query, it is declared to return record, rather than specifying any particular set of columns. This means that you must
specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```sql
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=','
  'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text)
WHERE proname LIKE 'bytea%';
```

The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what * should expand to, and what `proname` in the WHERE clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

**Notes**

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```sql
CREATE VIEW myremote_pg_proc AS
SELECT *
FROM dblink('dbname=postgres options=-csearch_path=','
  'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text);
```

```sql
SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

**Examples**

```sql
SELECT *
FROM dblink('dbname=postgres options=-csearch_path=','
  'select proname, prosrc from pg_proc')
AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
```

<table>
<thead>
<tr>

\textbf{dblink\_exec}

\textbf{Name}

dblink\_exec — executes a command in a remote database

\textbf{Synopsis}

dblink\_exec\(\text{text conname, text sql [, bool fail\_on\_error]}\) returns text
dblink\_exec\(\text{txt constr, text sql [, bool fail\_on\_error]}\) returns text
dblink\_exec\(\text{text sql [, bool fail\_on\_error]}\) returns text

\textbf{Description}

dblink\_exec executes a command (that is, any SQL statement that doesn’t return rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for \texttt{dblink\_connect}, and the indicated connection is made just for the duration of this command.

\textbf{Arguments}

\texttt{conname} \\
Name of the connection to use; omit this parameter to use the unnamed connection.

\texttt{constr} \\
A connection info string, as previously described for \texttt{dblink\_connect}.

\texttt{sql} \\
The SQL command that you wish to execute in the remote database, for example \texttt{insert into foo values\(0,\text{’a’,’\{”a0”,”b0”,”c0”\}’}\). 

\texttt{fail\_on\_error} \\
If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to \texttt{ERROR}.

\textbf{Return Value}

Returns status, either the command’s status string or \texttt{ERROR}.  

2434
Examples

```sql
SELECT dblink_connect('dbname=dblink_test_standby');
  dblink_connect
--------------------
   OK
(1 row)

SELECT dblink_exec('insert into foo values(21,"z","{"a0","b0","c0"}");');
  dblink_exec
-----------------
   INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
--------------------
   OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21,"z","{"a0","b0","c0"}");');
  dblink_exec
------------------
   INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values ("foo")',false);
NOTICE: sql error
DETAIL: ERROR: null value in column "relnamespace" violates not-null constraint
  dblink_exec
-------------
   ERROR
(1 row)
```
**dblink_open**

**Name**

`dblink_open` — opens a cursor in a remote database

**Synopsis**

`dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text`

`dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text`

**Description**

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

**Arguments**

- `connname`
  - Name of the connection to use; omit this parameter to use the unnamed connection.

- `cursorname`
  - The name to assign to this cursor.

- `sql`
  - The SELECT statement that you wish to execute in the remote database, for example `select * from pg_class`.

- `fail_on_error`
  - If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to `ERROR`.

**Return Value**

Returns status, either `OK` or `ERROR`.

**Notes**

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec`
to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change will be lost because the transaction will be aborted.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
-- dblink_connect
----------
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
-- dblink_open
----------
 OK
(1 row)
```
**dblink_fetch**

**Name**

`dblink_fetch` — returns rows from an open cursor in a remote database

**Synopsis**

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) returns setof record
```

**Description**

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

**Arguments**

**connname**

Name of the connection to use; omit this parameter to use the unnamed connection.

**cursorname**

The name of the cursor to fetch from.

**howmany**

The maximum number of rows to retrieve. The next `howmany` rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

**fail_on_error**

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

**Notes**

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still
advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote \texttt{FETCH} has been done.

\textbf{Examples}

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
\texttt{dblink connect}
----------------
\texttt{OK}
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like "bytea%"');

```
dblink_close

Name
dblink_close — closes a cursor in a remote database

Synopsis
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text

Description
dblink_close closes a cursor previously opened with dblink_open.

Arguments

connname
  Name of the connection to use; omit this parameter to use the unnamed connection.
cursorname
  The name of the cursor to close.
fail_on_error
  If true (the default when omitted) then an error thrown on the remote side of the connection causes
  an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the
  function’s return value is set to ERROR.

Return Value

Returns status, either OK or ERROR.

Notes

If dblink_open started an explicit transaction block, and this is the last remaining open cursor in this
connection, dblink_close will issue the matching COMMIT.

Examples

SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
---
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
-------------
OK
(1 row)

SELECT dblink_close('foo');
  dblink_close
-------------
OK
(1 row)
dblink_get_connections

Name
dblink_get_connections — returns the names of all open named dblink connections

Synopsis
dblink_get_connections() returns text[]

Description
dblink_get_connections returns an array of the names of all open named dblink connections.

Return Value
Returns a text array of connection names, or NULL if none.

Examples
SELECT dblink_get_connections();
dblink_error_message

Name
dblink_error_message — gets last error message on the named connection

Synopsis
dblink_error_message(text connname) returns text

Description
dblink_error_message fetches the most recent remote error message for a given connection.

Arguments
connname
   Name of the connection to use.

Return Value
Returns last error message, or OK if there has been no error in this connection.

Notes
When asynchronous queries are initiated by dblink_send_query, the error message associated with the connection might not get updated until the server’s response message is consumed. This typically means that dblink_is_busy or dblink_get_result should be called prior to dblink_error_message, so that any error generated by the asynchronous query will be visible.

Examples
SELECT dblink_error_message('dtest1');
dblink_send_query

Name
dblink_send_query — sends an async query to a remote database

Synopsis
dblink_send_query(text connname, text sql) returns int

Description
dblink_send_query sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with dblink_is_busy, and the results are ultimately collected with dblink_get_result. It is also possible to attempt to cancel an active async query using dblink_cancel_query.

Arguments

connname
    Name of the connection to use.

sql
    The SQL statement that you wish to execute in the remote database, for example select * from pg_class.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
dblink_is_busy

Name

dblink_is_busy — checks if connection is busy with an async query

Synopsis

dblink_is_busy(text connname) returns int

Description

dblink_is_busy tests whether an async query is in progress.

Arguments

connname
    Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that
dblink_get_result will not block.

Examples

SELECT dblink_is_busy('dtest1');
**dblink_get_notify**

**Name**

dblink_get_notify — retrieve async notifications on a connection

**Synopsis**

dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra text)

**Description**

dblink_get_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see LISTEN and NOTIFY.

**Arguments**

cconnname

The name of a named connection to get notifications on.

**Return Value**

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

**Examples**

```sql
SELECT dblink_exec('LISTEN virtual');
   dblink_exec
-----------
   LISTEN
(1 row)

SELECT * FROM dblink_get_notify();
   notify_name | be_pid | extra
------------+--------+-------
(0 rows)

NOTIFY virtual;
NOTIFY
```
SELECT * FROM dblink_get_notify();

<table>
<thead>
<tr>
<th>notify_name</th>
<th>be_pid</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>virtual</td>
<td>1229</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)
**dblink_get_result**

**Name**

dblink_get_result — gets an async query result

**Synopsis**

dblink_get_result(text connname [, bool fail_on_error]) returns setof record

**Description**

dblink_get_result collects the results of an asynchronous query previously sent with dblink_send_query. If the query is not already completed, dblink_get_result will wait until it is.

**Arguments**

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for dblink.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command’s status string. It is still necessary to specify that the result will have a single text column in the calling FROM clause.

**Notes**

This function must be called if dblink_send_query returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using dblink_send_query and dblink_get_result, dblink fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a
cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

**Examples**

```sql
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
  dblink_connect
----------------
        OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS t1;
  t1
  ----
       1
(1 row)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
     f1 |   f2 |  f3
    ----+-----+--------
      0 |   a | {a0,b0,c0}
      1 |   b | {a1,b1,c1}
      2 |   c | {a2,b2,c2}
(3 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text[]);
     f1 |   f2 |  f3
    ----+-----+--------
      0 |   a | {a0,b0,c0}
      1 |   b | {a1,b1,c1}
      2 |   c | {a2,b2,c2}
      7 |   h | {a7,b7,c7}
      8 |   i | {a8,b8,c8}
(3 rows)
```
9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(4 rows)

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text);
f1 | f2 | f3
----+----+----
(0 rows)
dblink_cancel_query

Name

dblink_cancel_query — cancels any active query on the named connection

Synopsis

dblink_cancel_query(text connname) returns text

Description

dblink_cancel_query attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling dblink_get_result.

Arguments

connname

Name of the connection to use.

Return Value

Returns OK if the cancel request has been sent, or the text of an error message on failure.

Examples

SELECT dblink_cancel_query('dtest1');
dblink_get_pkey

Name
dblink_get_pkey — returns the positions and field names of a relation’s primary key fields

Synopsis
dblink_get_pkey(text relname) returns setof dblink_pkey_results

Description
dblink_get_pkey provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments
relname
   Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

Return Value
Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

CREATE TYPE dblink_pkey_results AS (position int, colname text);

The position column simply runs from 1 to N; it is the number of the field within the primary key, not the number within the table’s columns.

Examples
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE
### dblink_get_pkey

```
SELECT * FROM dblink_get_pkey('foobar');
   position | colname
----------+--------
          1 | f1
          2 | f2
          3 | f3
(3 rows)
```
dblink_build_sql_insert

Name
dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis
dblink_build_sql_insert(text relname,
    int2vector primary_key_attnums,
    integer num_primary_key_atts,
    text[] src_pk_att_vals_array,
    text[] tgt_pk_att_vals_array) returns text

Description
dblink_build_sql_insert can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname
Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

primary_key_attnums
Attribute numbers (1-based) of the primary key fields, for example 1 2.

num_primary_key_atts
The number of primary key fields.

src_pk_att_vals_array
Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array
Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.
Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '1", "a"}', '{"1", "b"a"}');
```

```
---
INSERT INTO foo(f1,f2,f3) VALUES('1','b"a','1')
(1 row)
```
dblink_build_sql_delete

Name

dblink_build_sql_delete — builds a DELETE statement using supplied values for primary key field values

Synopsis

dblink_build_sql_delete(text relname,
        int2vector primary_key_attnums,
        integer num_primary_key_atts,
        text[] tgt_pk_att_vals_array) returns text

Description

dblink_build_sql_delete can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

Arguments

rename

Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example 1 2.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.
Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```sql
SELECT dblink_build_sql_delete('"MyFoo"', '1 2', 2, '{"1", "b"}');
```

```
dblink_build_sql_delete

DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
```

(1 row)
**dblink_build_sql_update**

**Name**

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_update(text relname,
   int2vector primary_key_attnums,
   integer num_primary_key_atts,
   text[] src_pk_att_vals_array,
   text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_update can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and dblink_build_sql_insert is that it’s assumed that the target row already exists in the remote table.

**Arguments**

**relname**

Name of a local relation, for example *foo* or *myschema.mytab*. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**primary_key_attnums**

Attribute numbers (1-based) of the primary key fields, for example 1 2.

**num_primary_key_atts**

The number of primary key fields.

**src_pk_att_vals_array**

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

**tgt_pk_att_vals_array**

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.
Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '({"1", "a"})', '({"1", "b"})');
```

```
UPDATE foo SET f1='1', f2='b', f3='1' WHERE f1='1' AND f2='b'
(1 row)
```
F.10. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

F.10.1. Configuration

The dictionary accepts two options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

F.10.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```
F.11. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.11.1. Configuration

A dict_xsyn dictionary accepts the following options:

- matchorig controls whether the original word is accepted by the dictionary. Default is true.
- matchesynonyms controls whether the synonyms are accepted by the dictionary. Default is false.
- keeporig controls whether the original word is included in the dictionary’s output. Default is true.
- keepsynonyms controls whether the synonyms are included in the dictionary’s output. Default is true.
- rules is the base name of the file containing the list of synonyms. This file must be stored in $SHAREDIR/tsearch_data/ (where $SHAREDIR means the PostgreSQL installation’s shared-data directory). Its name must end in .rules (which is not to be included in the rules parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:
  
  word syn1 syn2 syn3

- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at xsyn_sample.rules, which is installed in $SHAREDIR/tsearch_data/., for an example.

F.11.2. Usage

Installing the dict_xsyn extension creates a text search template xsyn_template and a dictionary xsyn based on it, with default parameters. You can alter the parameters, for example

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);

or create new dictionaries based on the template.

To test the dictionary, you can try

mydb=# SELECT ts_lexize('xsyn', 'word');

```sql
<table>
<thead>
<tr>
<th>ts_lexize</th>
</tr>
</thead>
<tbody>
<tr>
<td>{syn1,syn2,syn3}</td>
</tr>
</tbody>
</table>
```

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);

ALTER TEXT SEARCH DICTIONARY
Appendix F. Additional Supplied Modules

mydb=# SELECT ts_lexize('xsyn', 'word');
  ts_lexize
--------------------
{word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false, MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  ts_lexize
--------------------
{syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
  ts_lexize
--------------------
{word}

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR word, asciiword WITH xsyn, english Stem;

F.12. earthdistance

The earthdistance module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the cube module (which must be installed before earthdistance can be installed). The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that’s too inaccurate for you, you might want to look at the PostGIS project.)

F.12.1. Cube-based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain earth over cube is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

1. http://postgis.net/
Appendix F. Additional Supplied Modules

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of \(180/\pi\) so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F-6.

Table F-6. Cube-based Earthdistance Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>earth()</code></td>
<td>float8</td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td><code>sec_to_gc(float8)</code></td>
<td>float8</td>
<td>Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.</td>
</tr>
<tr>
<td><code>gc_to_sec(float8)</code></td>
<td>float8</td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
<tr>
<td><code>ll_to_earth(float8, float8)</code></td>
<td>earth</td>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
<tr>
<td><code>latitude(earth)</code></td>
<td>float8</td>
<td>Returns the latitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td><code>longitude(earth)</code></td>
<td>float8</td>
<td>Returns the longitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td><code>earth_distance(earth, earth)</code></td>
<td>float8</td>
<td>Returns the great circle distance between two points on the surface of the Earth.</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>earth_box(earth, float8)</td>
<td>cube</td>
<td>Returns a box suitable for an indexed search using the cube @&gt; operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using earth_distance should be included in the query.</td>
</tr>
</tbody>
</table>

F.12.2. Point-based Earth Distances

The second part of the module relies on representing Earth locations as values of type point, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F-7.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point &lt;@&gt; point</td>
<td>float8</td>
<td>Gives the distance in statute miles between two points on the Earth’s surface.</td>
</tr>
</tbody>
</table>

Note that unlike the cube-based part of the module, units are hardwired here: changing the earth() function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The cube-based representation avoids these discontinuities.

F.13. file_fdw

The file_fdw module provides the foreign-data wrapper file_fdw, which can be used to access data files in the server’s file system. Data files must be in a format that can be read by COPY FROM; see COPY for details. Access to such data files is currently read-only.

A foreign table created using this wrapper can have the following options:

filename

Specifies the file to be read. Required. Must be an absolute path name.
Appendix F. Additional Supplied Modules

format

Specifies the file’s format, the same as COPY’s FORMAT option.

header

Specifies whether the file has a header line, the same as COPY’s HEADER option.

delimiter

Specifies the file’s delimiter character, the same as COPY’s DELIMITER option.

quote

Specifies the file’s quote character, the same as COPY’s QUOTE option.

escape

Specifies the file’s escape character, the same as COPY’s ESCAPE option.

null

Specifies the file’s null string, the same as COPY’s NULL option.

encoding

Specifies the file’s encoding, the same as COPY’s ENCODING option.

Note that while COPY allows options such as OIDS and HEADER to be specified without a corresponding value, the foreign data wrapper syntax requires a value to be present in all cases. To activate COPY options normally supplied without a value, you can instead pass the value TRUE.

A column of a foreign table created using this wrapper can have the following options:

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the file-level null option). This has the same effect as listing the column in COPY’s FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY’s FORCE_NULL option.

COPY’s OIDS and FORCE_QUOTE options are currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires superuser privileges, for security reasons: only a superuser should be able to determine which file is read. In principle non-superusers could be allowed to change the other options, but that’s not supported at present.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read. Unless COSTS OFF is specified, the file size (in bytes) is shown as well.
Example F-1. Create a Foreign Table for PostgreSQL CSV Logs

One of the obvious uses for the `file_fdw` is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```sql
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```sql
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```sql
CREATE FOREIGN TABLE pglog (
    log_time timestamp(3) with time zone,
    user_name text,
    database_name text,
    process_id integer,
    connection_from text,
    session_id text,
    session_line_num bigint,
    command_tag text,
    session_start_time timestamp with time zone,
    virtual_transaction_id text,
    transaction_id bigint,
    error_severity text,
    sql_state_code text,
    message text,
    detail text,
    hint text,
    internal_query text,
    internal_query_pos integer,
    context text,
    query text,
    query_pos integer,
    location text,
    application_name text
) SERVER pglog
OPTIONS ( filename '/home/josh/9.1/data/pg_log/pglog.csv', format 'csv' );
```

That’s it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.14. fuzzystrmatch

The `fuzzystrmatch` module provides several functions to determine similarities and distance between strings.
Appendix F. Additional Supplied Modules

Caution
At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8).

F.14.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

soundex(text) returns text
difference(text, text) returns int

The soundex function converts a string to its Soundex code. The difference function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — similarity would have been a better name.)

Here are some usage examples:

SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;

F.14.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns int
levenshtein(text source, text target) returns int
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int sub_cost, int max_d) returns int
Both source and target can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

levenshtein_less_equal is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to max_d, then levenshtein_less_equal returns the correct distance; otherwise it returns some value greater than max_d. If max_d is negative then the behavior is the same as levenshtein.

Examples:

```
SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
------------
  2
(1 row)

SELECT levenshtein('GUMBO', 'GAMBOL', 2,1,1);
levenshtein
------------
   3
(1 row)

SELECT levenshtein_less_equal('extensive', 'exhaustive',2);
levenshtein_less_equal
-----------------------
     3
(1 row)

SELECT levenshtein_less_equal('extensive', 'exhaustive',4);
levenshtein_less_equal
-----------------------
     4
(1 row)
```

F.14.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

source has to be a non-null string with a maximum of 255 characters. max_output_length sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
SELECT metaphone('GUMBO', 4);
metaphone
```
F.14.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

\[
\text{dmetaphone(text source) returns text}
\]
\[
\text{dmetaphone_alt(text source) returns text}
\]

There is no length limit on the input strings.

Example:

```
test=# select dmetaphone('gumbo');
```

F.15. hstore

This module implements the \texttt{hstore} data type for storing sets of key/value pairs within a single PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

F.15.1. hstore External Representation

The text representation of an \texttt{hstore}, used for input and output, includes zero or more \texttt{key => value} pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the \texttt{=} sign is ignored. Double-quote keys and values that include whitespace, commas, =s or >s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an \texttt{hstore} is unique. If you declare an \texttt{hstore} with duplicate keys, only one will be stored in the \texttt{hstore} and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2':::hstore;
```

\[
\text{hstore}
\]
Appendix F. Additional Supplied Modules
---------"a"=>"1"

A value (but not a key) can be an SQL NULL. For example:
key => NULL

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.
Note: Keep in mind that the hstore text format, when used for input, applies before any required
quoting or escaping. If you are passing an hstore literal via a parameter, then no additional processing is needed. But if you’re passing it as a quoted literal constant, then any single-quote characters
and (depending on the setting of the standard_conforming_strings configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string
constants.

On output, double quotes always surround keys and values, even when it’s not strictly necessary.

F.15.2. hstore Operators and Functions
The operators provided by the hstore module are shown in Table F-8, the functions in Table F-9.
Table F-8. hstore Operators
Operator

Description

Example

Result

hstore -> text

get value for key (NULL
if not present)

’a=>x,
b=>y’::hstore ->
’a’

x

hstore -> text[]

get values for keys
(NULL if not present)

’a=>x, b=>y,
c=>z’::hstore ->
ARRAY[’c’,’a’]

{"z","x"}

hstore || hstore

concatenate hstores

’a=>b,
c=>d’::hstore ||
’c=>x,
d=>q’::hstore

"a"=>"b",
"c"=>"x",
"d"=>"q"

hstore ? text

does hstore contain
key?

’a=>1’::hstore ?
’a’

t

hstore ?& text[]

does hstore contain all ’a=>1,b=>2’::hstoret
specified keys?
?& ARRAY[’a’,’b’]

hstore ?| text[]

does hstore contain
any of the specified
keys?

’a=>1,b=>2’::hstoret

Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>populate_record</td>
<td>record</td>
<td>replace fields in record with matching values from hstore</td>
<td>see Examples</td>
<td>section</td>
</tr>
</tbody>
</table>

**Note:** The function hstore_to_json is used when an hstore value is cast to json. Likewise, hstore_to_jsonb is used when an hstore value is cast to jsonb.

**Note:** The function populate_record is actually declared with anyelement, not record, as its first argument, but it will reject non-record types with a run-time error.

F.15.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

CREATE INDEX hidx ON testhstore USING GIST (h);

CREATE INDEX hidx ON testhstore USING GIN (h);

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

CREATE INDEX hidx ON testhstore USING BTREE (h);

CREATE INDEX hidx ON testhstore USING HASH (h);

F.15.4. Examples

Add a key, or update an existing key with a new value:

UPDATE tab SET h = h || hstore(‘c’, ‘3’);

Delete a key:

UPDATE tab SET h = delete(h, ‘k1’);

Convert a record to an hstore:
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT hstore(t) FROM test AS t;
     hstore
---------------------------------------------
   "col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)

Convert an hstore to a predefined record type:

CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
     '"col1"=>"456", "col2"=>"zzz"');

  col1 | col2 | col3
----------+-------+------
     456 |   zzz |
(1 row)

Modify an existing record using the values from an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;

  col1 | col2 | col3
----------+-------+------
    123 |   foo |   baz
(1 row)

F.15.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');

Using a table:

SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

<table>
<thead>
<tr>
<th>key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>883</td>
</tr>
<tr>
<td>query</td>
<td>207</td>
</tr>
<tr>
<td>pos</td>
<td>203</td>
</tr>
<tr>
<td>node</td>
<td>202</td>
</tr>
<tr>
<td>space</td>
<td>197</td>
</tr>
<tr>
<td>status</td>
<td>195</td>
</tr>
<tr>
<td>public</td>
<td>194</td>
</tr>
<tr>
<td>title</td>
<td>190</td>
</tr>
<tr>
<td>org</td>
<td>189</td>
</tr>
</tbody>
</table>

F.15.6. Compatibility

As of PostgreSQL 9.0, hstore uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an UPDATE statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || ";
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || ";
```

The ALTER TABLE method requires an exclusive lock on the table, but does not result in bloating the table with old row versions.

F.15.7. Transforms

Additional extensions are available that implement transforms for the hstore type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called hstore_plperl and hstore_plperlu, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, hstore values are mapped to Perl hashes. The extensions for PL/Python are called
Appendix F. Additional Supplied Modules

hstore_plpythonu, hstore_plpython2u, and hstore_plpython3u (see Section 43.1 for the PL/Python naming convention). If you use them, hstore values are mapped to Python dictionaries.

F.15.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia
Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia
Additional enhancements by Andrew Gierth <andrew@taol1.riddles.org.uk>, United Kingdom

F.16. intagg

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.16.1. Functions

The aggregator is an aggregate function int_array_aggregate(integer) that produces an integer array containing exactly the integers it is fed. This is a wrapper around array_agg, which does the same thing for any array type.

The enumerator is a function int_array_enum(integer[]) that returns setof integer. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around unnest, which does the same thing for any array type.

F.16.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);

It is typically used like this:

SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the one_to_many table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table.
for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```sql
CREATE TABLE summary AS
    SELECT left, int_array_aggregate(right) AS right
    FROM one_to_many
    GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that’s why there is an array enumerator. You can do

```sql
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```sql
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```sql
SELECT right, count(right) FROM
    ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
    ) AS list
GROUP BY right
ORDER BY count DESC;
```

### F.17. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

#### F.17.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in Table F-10, the operators in Table F-11.
### Appendix F. Additional Supplied Modules

<tr>
<td>query_int ~~ int[]</td>
<td>boolean</td>
<td>true if array satisfies query (commutator of @@)</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators @> and <@ were respectively called @ and ~. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators @@, @> and <@ are equivalent to PostgreSQL's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The @@ and ~~ operators test whether an array satisfies a query, which is expressed as a value of a specialized data type query_int. A query consists of integer values that are checked against the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query 1& (2|3) matches arrays that contain 1 and also contain either 2 or 3.

### F.17.2. Index Support

`intarray` provides index support for the @@, @>, <@, and ~@ operators, as well as regular array equality.

Two GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.
F.17.3. Example

-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[]);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__int_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2':query_int;

F.17.4. Benchmark

The source directory contrib/intarray/bench contains a benchmark test suite. To run:

    cd .../bench
    createdb TEST
    psql TEST < ../_int.sql
    ./create_test.pl | psql TEST
    ./bench.pl

The bench.pl script has numerous options, which are displayed when it is run without any arguments.

F.17.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.18. isn

The isn module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtained the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.
F.18.1. Data Types

Table F-12 shows the data types provided by the isn module.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren’t always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it’s possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).
F.18.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.18.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F-13. In this table, isn means any one of the module’s data types.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak(boolean)</td>
<td>boolean</td>
<td>Sets the weak input mode (returns new setting)</td>
</tr>
<tr>
<td>isn_weak()</td>
<td>boolean</td>
<td>Gets the current status of the weak mode</td>
</tr>
<tr>
<td>make_valid(isn)</td>
<td>isn</td>
<td>Validates an invalid number (clears the invalid flag)</td>
</tr>
<tr>
<td>is_valid(isn)</td>
<td>boolean</td>
<td>Checks for the presence of the invalid flag</td>
</tr>
</tbody>
</table>

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess...
Appendix F. Additional Supplied Modules

up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you’d want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

F.18.4. Examples

--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the ’?’):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');

SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;
F.18.5. Bibliography

The information to implement this module was collected from several sites, including:

- http://www.isbn-international.org/
- http://www.issn.org/
- http://www.ismn-international.org/
- http://www.wikipedia.org/

The prefixes used for hyphenation were also compiled from:

- http://www.gs1.org/productssolutions/idkeys/support/prefix_list.html
- https://www.isbn-international.org/content/isbn-users-manual
- http://www.ismn-international.org/ranges.html

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.18.6. Author

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman’s isbn_issn code.

F.19. lo

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

F.19.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn’t occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same
large object OID, so the system doesn’t delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won’t delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain of the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don’t have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don’t use lo for BLOB columns.

F.19.2. How to Use It

Here’s a simple example of usage:

```sql
CREATE TABLE image (title TEXT, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE PROCEDURE lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.19.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the DROP TABLE with DELETE FROM table.

  TRUNCATE has the same hazard.

  If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It’s a good idea to run vacuumlo occasionally as a back-stop to the lo_manage trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.
Appendix F. Additional Supplied Modules

F.19.4. Author

Peter Mount <peter@retep.org.uk>

F.20. ltree

This module implements a data type ltree for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

F.20.1. Definitions

A label is a sequence of alphanumeric characters and underscores (for example, in C locale the characters A-Za-z0-9_ are allowed). Labels must be less than 256 bytes long.

Examples: 42, Personal_Services

A label path is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path must be less than 65Kb, but keeping it under 2Kb is preferable.

Example: Top.Countries.Europe.Russia

The ltree module provides several data types:

- ltree stores a label path.
- lquery represents a regular-expression-like pattern for matching ltree values. A simple word matches that label within a path. A star symbol (*) matches zero or more labels. For example:

  foo Match the exact label path foo
  *.foo.* Match any label path containing the label foo
  *.foo Match any label path whose last label is foo

Star symbols can also be quantified to restrict how many labels they can match:

  *{n} Match exactly n labels
  *{n,} Match at least n labels
  *{n,m} Match at least n but not more than m labels
  *{,m} Match at most m labels -- same as *{0,m}

There are several modifiers that can be put at the end of a non-star label in lquery to make it match more than just the exact match:

  @ Match case-insensitively, for example a@ matches A
  * Match any label with this prefix, for example foo* matches foobar
  % Match initial underscore-separated words

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example foo_bar% matches foo_bar_baz but not foo_barbax. If combined with *, prefix matching applies to each word separately, for example foo_bar%* matches fool_bar2_baz but not fool_br2_baz.

Also, you can write several possibly-modified labels separated with | (OR) to match any of those labels, and you can put ! (NOT) at the start to match any label that doesn’t match any of the alternatives.
Here’s an annotated example of \texttt{lquery}:

\texttt{Top.*\{0,2\}.sport@!football|tennis.Russ*|Spain}

a. b. c. d. e.

This query will match any label path that:

a. begins with the label \texttt{Top}

b. and next has zero to two labels before

c. a label beginning with the case-insensitive prefix \texttt{sport}

d. then a label not matching \texttt{football} nor \texttt{tennis}

e. and then ends with a label beginning with \texttt{Russ} or exactly matching \texttt{Spain}.

- \texttt{ltxtquery} represents a full-text-search-like pattern for matching \texttt{ltree} values. An \texttt{ltxtquery} value contains words, possibly with the modifiers \texttt{@}, \texttt{*}, \texttt{%} at the end; the modifiers have the same meanings as in \texttt{lquery}. Words can be combined with \texttt{&} (AND), \texttt{|} (OR), \texttt{!} (NOT), and parentheses. The key difference from \texttt{lquery} is that \texttt{ltxtquery} matches words without regard to their position in the label path.

Here’s an example \texttt{ltxtquery}:

\texttt{Europe \& Russia*@ \& !Transportation}

This will match paths that contain the label \texttt{Europe} and any label beginning with \texttt{Russia} (case-insensitive), but not paths containing the label \texttt{Transportation}. The location of these words within the path is not important. Also, when \texttt{%} is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: \texttt{ltxtquery} allows whitespace between symbols, but \texttt{ltree} and \texttt{lquery} do not.

### F.20.2. Operators and Functions

Type \texttt{ltree} has the usual comparison operators \texttt{=, <>, <, >, <=, >=}. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F-14 are available.

<table>

<tr>
<td><code>lquery[] ? ltree[]</code></td>
<td>boolean</td>
<td>does <code>ltree</code> array contain any path matching any <code>lquery</code>?</td>
</tr>
<tr>
<td><code>ltree[] @ ltxtquery</code></td>
<td>boolean</td>
<td>does array contain any path matching <code>ltxtquery</code>?</td>
</tr>
<tr>
<td><code>ltxtquery @ ltree[]</code></td>
<td>boolean</td>
<td>does array contain any path matching <code>ltxtquery</code>?</td>
</tr>
<tr>
<td><code>ltree[] ?&gt; ltree</code></td>
<td><code>ltree</code></td>
<td>first array entry that is an ancestor of <code>ltree</code>; NULL if none</td>
</tr>
<tr>
<td><code>ltree[] ?? ltree</code></td>
<td><code>ltree</code></td>
<td>first array entry that is a descendant of <code>ltree</code>; NULL if none</td>
</tr>
<tr>
<td><code>ltree[] ~ lquery</code></td>
<td><code>ltree</code></td>
<td>first array entry that matches <code>lquery</code>; NULL if none</td>
</tr>
<tr>
<td><code>ltree[] ?@ ltxtquery</code></td>
<td><code>ltree</code></td>
<td>first array entry that matches <code>ltxtquery</code>; NULL if none</td>
</tr>
</tbody>
</table>

The operators `<@, @>, @ and ~ have analogues `^<@, ^@>, ^@, ^~`, which are the same except they do not use indexes. These are useful only for testing purposes.
The available functions are shown in Table F-15.

### Table F-15. `ltree` Functions

<table>
<thead>
<tr>

</tbody>
</table>

#### F.20.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- **B-tree index over `ltree`:** `<, <=, =, >, >=`  
  Example of creating such an index:  
  ```sql
  CREATE INDEX path_gist_idx ON test USING GIST (path);
  ```

- **GiST index over `ltree`:** `<, <=, =, >, >, @, <>, @, ~, ?`  
  Example of creating such an index:  
  ```sql
  CREATE INDEX path_gist_idx ON test USING GIST (array_path);
  ```
  Note: This index type is lossy.

#### F.20.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```sql
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

2491
CREATE INDEX path_idx ON test USING BTREE (path);

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
Top
 / | \  
Science Hobbies Collections
 / | \  
Astronomy Amateurs_Astronomy Pictures
 / \ |   \  
Astrophysics Cosmology Astronomy
 / | \  
Galaxies Stars Astronauts
```

We can do inheritance:

```
lvreeetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
path
------------------------
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(4 rows)
```

Here are some examples of path matching:

```
lvreeetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
path
-----------------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Collections.Pictures.Astronomy
(7 rows)
lvreeetest=> SELECT path FROM test WHERE path ~ '*.!pictures@.*.Astronomy.*';
path
------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(3 rows)
```

Here are some examples of full text search:

```
lvreeetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
path
2492
```
Appendix F. Additional Supplied Modules

Path construction using functions:

```
SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@ 'Top.Science.Astronomy';
```

```
Top.Science.Space.Astronomy
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
SELECT ins_label(path,2,'Space') FROM test WHERE path <@ 'Top.Science.Astronomy';
```

```
Top.Science.Space.Astronomy
(3 rows)
```

F.20.5. Transforms

Additional extensions are available that implement transforms for the ltree type for PL/Python. The extensions are called ltree_plpythonu, ltree_plpython2u, and ltree_plpython3u (see Section 43.1 for the PL/Python naming convention). If you install these transforms and specify them when creating a function, ltree values are mapped to Python lists. (The reverse is currently not supported, however.)
Appendix F. Additional Supplied Modules

F.20.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.21. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.21.1. Functions

```
get_raw_page(relname text, fork text, blkno int) returns bytea
```

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

```
get_raw_page(relname text, blkno int) returns bytea
```

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`.

```
page_header(page bytea) returns record
```

`page_header` shows fields that are common to all PostgreSQL heap and index pages. A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));

  lsn | checksum | flags | lower | upper | special | pagesize | version | prune_xid
  ------+----------+--------+-------+-------+---------+----------+---------+-----------
    0/24A1B50 | 2 | 1 | 232 | 368 | 8192 | 8192 | 4 | 
```

The returned columns correspond to the fields in the `PageHeaderData` struct. See `src/include/storage/bufpage.h` for details.

```
heap_page_items(page bytea) returns setof record
```

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

See `src/include/storage/itemid.h` and `src/include/access/htup_details.h` for explanations of the fields returned.
bt_metap(relname text) returns record

bt_metap returns information about a B-tree index’s metapage. For example:

```sql
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-| RECORD 1 |
|-----
magic | 340322
version | 2
root | 1
level | 0
fastroot | 1
fastlevel | 0
```

bt_page_stats(relname text, blkno int) returns record

bt_page_stats returns summary information about single pages of B-tree indexes. For example:

```sql
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-| RECORD 1 |
|-----
blkno | 1
type | l
live_items | 256
dead_items | 0
avg_item_size | 12
page_size | 8192
free_size | 4056
btpo_prev | 0
btpo_next | 0
btpo | 0
btpo_flags | 3
```

bt_page_items(relname text, blkno int) returns setof record

bt_page_items returns detailed information about all of the items on a B-tree index page. For example:

```sql
test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
itemoffset | ctid | itemlen | nulls | vars | data
------------+---------+---------+-------+------+-------------
1 | (0,1) | 12 | f | f | 23 27 00 00
2 | (0,2) | 12 | f | f | 24 27 00 00
3 | (0,3) | 12 | f | f | 25 27 00 00
4 | (0,4) | 12 | f | f | 26 27 00 00
5 | (0,5) | 12 | f | f | 27 27 00 00
6 | (0,6) | 12 | f | f | 28 27 00 00
7 | (0,7) | 12 | f | f | 29 27 00 00
8 | (0,8) | 12 | f | f | 2a 27 00 00
```

In a B-tree leaf page, ctid points to a heap tuple. In an internal page, the block number part of ctid points to another page in the index itself, while the offset part (the second number) is ignored and is usually 1.

Note that the first item on any non-rightmost page (any page with a non-zero value in the btpo_next field) is the page’s “high key”, meaning its data serves as an upper bound on all items appearing on the page, while its ctid field is meaningless. Also, on non-leaf pages, the first real data item (the first item that is not a high key) is a “minus infinity” item, with no actual value in its data field. Such an item does have a valid downlink in its ctid field, however.
Appendix F. Additional Supplied Modules

`brin_page_type(page bytea) returns text`

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```
test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
```

```
brin_page_type
----------------
meta
```

`brin_metapage_info(page bytea) returns record`

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
```

```
magic | version | pagesperrange | lastrevmappage
-------+---------+---------------+----------------
0xA8109CFA | 1 | 4 | 2
```

```
brin_revmap_data(page bytea) returns setof tid`

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) limit 5;
```

```
pages
---------
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

```
brin_page_items(page bytea, index oid) returns setof record`

`brin_page_items` returns the data stored in the BRIN data page. For example:

```
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5), 'brinidx')
```

```
ORDER BY blknum, attnum LIMIT 6;
```

```
itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
-----------+--------+--------+----------+----------+-------------+--------------
137 | 0 | 1 | t | f | f |
137 | 0 | 2 | f | f | f | {1 .. 88}
138 | 4 | 1 | t | f | f |
138 | 4 | 2 | f | f | f | {89 .. 176}
139 | 8 | 1 | t | f | f |
139 | 8 | 2 | f | f | f | {177 .. 264}
```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs. See `src/include/access/brin_tuple.h` for details.

```
gin_metapage_info(page bytea) returns record`

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
```

```
- [ RECORD 1 ]----------
pending_head | 4294967295
pending_tail | 4294967295
tail_free_size | 0
```

2496
gin_page_opaque_info(page bytea) returns record

gin_page_opaque_info returns information about a GIN index opaque area, like the page type. For example:

test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));

<table>
<thead>
<tr>
<th>rightlink</th>
<th>maxoff</th>
<th>flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>0</td>
<td>{data,leaf,compressed}</td>
</tr>
</tbody>
</table>

1 row

gin_leafpage_items(page bytea) returns setof record

gin_leafpage_items returns information about the data stored in a GIN leaf page. For example:

test=# SELECT first_tid, nbytes, tids[0:5] as some_tids FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));

<table>
<thead>
<tr>
<th>first_tid</th>
<th>nbytes</th>
<th>some_tids</th>
</tr>
</thead>
<tbody>
<tr>
<td>(8,41)</td>
<td>244</td>
<td>{&quot;(8,41)&quot;,&quot;(8,43)&quot;,&quot;(8,44)&quot;,&quot;(8,45)&quot;,&quot;(8,46)&quot;}</td>
</tr>
<tr>
<td>(10,45)</td>
<td>248</td>
<td>{&quot;(10,45)&quot;,&quot;(10,46)&quot;,&quot;(10,47)&quot;,&quot;(10,48)&quot;,&quot;(10,49)&quot;}</td>
</tr>
<tr>
<td>(12,52)</td>
<td>248</td>
<td>{&quot;(12,52)&quot;,&quot;(12,53)&quot;,&quot;(12,54)&quot;,&quot;(12,55)&quot;,&quot;(12,56)&quot;}</td>
</tr>
<tr>
<td>(14,59)</td>
<td>320</td>
<td>{&quot;(14,59)&quot;,&quot;(14,60)&quot;,&quot;(14,61)&quot;,&quot;(14,62)&quot;,&quot;(14,63)&quot;}</td>
</tr>
<tr>
<td>(167,16)</td>
<td>376</td>
<td>{&quot;(167,16)&quot;,&quot;(167,17)&quot;,&quot;(167,18)&quot;,&quot;(167,19)&quot;,&quot;(167,20)&quot;}</td>
</tr>
<tr>
<td>(170,30)</td>
<td>376</td>
<td>{&quot;(170,30)&quot;,&quot;(170,31)&quot;,&quot;(170,32)&quot;,&quot;(170,33)&quot;,&quot;(170,34)&quot;}</td>
</tr>
<tr>
<td>(173,44)</td>
<td>197</td>
<td>{&quot;(173,44)&quot;,&quot;(173,45)&quot;,&quot;(173,46)&quot;,&quot;(173,47)&quot;,&quot;(173,48)&quot;}</td>
</tr>
</tbody>
</table>

7 rows

fsm_page_contents(page bytea) returns text

fsm_page_contents shows the internal node structure of a FSM page. The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

See src/backend/storage/freespace/README for more information on the structure of an FSM page.

F.22. passwordcheck

The passwordcheck module checks users' passwords whenever they are set with CREATE ROLE or ALTER ROLE. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '$libdir/passwordcheck' to shared_preload_libraries in postgresql.conf, then restart the server.
You can adapt this module to your needs by changing the source code. For example, you can use CrackLib\(^2\) to check passwords — this only requires uncommenting two lines in the Makefile and rebuilding the module. (We cannot include CrackLib by default for license reasons.) Without CrackLib, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

---

**Caution**

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the passwordcheck module, because in that case it can only try to guess the password. For this reason, passwordcheck is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 19) than to rely on passwords within the database.

Alternatively, you could modify passwordcheck to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

---

### F.23. pg_buffercache

The pg_buffercache module provides a means for examining what’s happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default public access is revoked from both of these, just in case there are security issues lurking.

#### F.23.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in Table F-16.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bufferid</td>
<td>integer</td>
<td></td>
<td>ID, in the range 1..shared_buffers</td>
</tr>
<tr>
<td>relfilenode</td>
<td>oid</td>
<td>pg_class.relfilenode</td>
<td>Filenode number of the relation</td>
</tr>
<tr>
<td>reltablespace</td>
<td>oid</td>
<td>pg_tablespace.oid</td>
<td>Tablespace OID of the relation</td>
</tr>
<tr>
<td>reldatabase</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>Database OID of the relation</td>
</tr>
</tbody>
</table>

---

\(^2\) [http://sourceforge.net/projects/cracklib/](http://sourceforge.net/projects/cracklib/)
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relforknumber</td>
<td>smallint</td>
<td></td>
<td>Fork number within the relation; see include/common/relpath.h</td>
</tr>
<tr>
<td>relblocknumber</td>
<td>bigint</td>
<td></td>
<td>Page number within the relation</td>
</tr>
<tr>
<td>isdirty</td>
<td>boolean</td>
<td></td>
<td>Is the page dirty?</td>
</tr>
<tr>
<td>usagecount</td>
<td>smallint</td>
<td></td>
<td>Clock-sweep access count</td>
</tr>
<tr>
<td>pinning_backends</td>
<td>integer</td>
<td></td>
<td>Number of backends pinning this buffer</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except bufferid. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in pg_class for some rows, or that there could even be incorrect joins. If you are trying to join against pg_class, it's a good idea to restrict the join to rows having reldatabase equal to the current database's OID or zero.

When the pg_buffercache view is accessed, internal buffer manager locks are taken for long enough to copy all the buffer state data that the view will display. This ensures that the view produces a consistent set of results, while not blocking normal buffer activity longer than necessary. Nonetheless there could be some impact on database performance if this view is read often.

F.23.2. Sample Output

```
regression=# SELECT c.relname, count(*) AS buffers
           FROM pg_buffercache b INNER JOIN pg_class c
           ON b.relfilenode = pg_relation_filenode(c.oid) AND
              b.reldatabase IN (0, (SELECT oid FROM pg_database
                                      WHERE datname = current_database()))
           GROUP BY c.relname
           ORDER BY 2 DESC
           LIMIT 10;

relname      | buffers

F.24. pgcrypto

The pgcrypto module provides cryptographic functions for PostgreSQL.

F.24.1. General Hashing Functions

F.24.1.1. digest()

digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea

Computes a binary hash of the given data. type is the algorithm to use. Standard algorithms are md5, sha1, sha224, sha256, sha384 and sha512. If pgcrypto was built with OpenSSL, more algorithms are available, as detailed in Table F-20.

If you want the digest as a hexadecimal string, use encode() on the result. For example:

CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;

F.24.1.2. hmac()

hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea

Calculates hashed MAC for data with key. type is the same as in digest().

This is similar to digest() but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.
F.24.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the `salt`, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F-17 lists the algorithms supported by the `crypt()` function.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>
<td>34</td>
<td>MD5-based crypt</td>
</tr>
<tr>
<td>xdes</td>
<td>8</td>
<td>yes</td>
<td>24</td>
<td>20</td>
<td>Extended DES</td>
</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>

F.24.2.1. `crypt()`

`crypt(password text, salt text) returns text`

Calculates a crypt(3)-style hash of `password`. When storing a new password, you need to use `gen_salt()` to generate a new `salt` value. To check a password, pass the stored hash value as `salt`, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;

This returns `true` if the entered password is correct.

**F.24.2.2. gen_salt()**

gen_salt(type text [, iter_count integer ]) returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The `type` parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The `iter_count` parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the `iter_count` parameter is omitted, the default iteration count is used. Allowed values for `iter_count` depend on the algorithm and are shown in Table F-18.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
<tr>
<td>bf</td>
<td>6</td>
<td>4</td>
<td>31</td>
</tr>
</tbody>
</table>

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F-19 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the `iter_count` parameter of `gen_salt`.

**Table F-19. Hash Algorithm Speeds**

</tbody>
</table>

Notes:

- The machine used is an Intel Mobile Core i3.
- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: john -test shows 213 loops/sec for crypt-bf/5. (The very small difference in results is in accordance with the fact that the crypt-bf implementation in pgcrypto is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.24.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or packets:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.
In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

**F.24.3.1. pgp_sym_encrypt()**

`pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea`
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea`

Encrypt data with a symmetric PGP key `psw`. The `options` parameter can contain option settings, as described below.

**F.24.3.2. pgp_sym_decrypt()**

`pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text`
`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

**F.24.3.3. pgp_pub_encrypt()**

`pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea`
`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea`

Encrypt data with a public PGP key `key`. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

**F.24.3.4. pgp_pub_decrypt()**

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text`
`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea`

Decrypt a public-key-encrypted message. `key` must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in `psw`. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.
Appendix F. Additional Supplied Modules

The options parameter can contain option settings, as described below.

**F.24.3.5. pgp_key_id()**

pgp_key_id(bytea) returns text

pgp_key_id extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**
  The message is encrypted with a symmetric key.

- **ANYKEY**
  The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. pgcrypto itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling ANYKEY.

**F.24.3.6. armor(), dearmor()**

armor(data bytea [ , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the keys and values arrays are specified, an armor header is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

**F.24.3.7. pgp_armor_headers**

pgp_armor_headers(data text, key out text, value out text) returns setof record

pgp_armor_headers() extracts the armor headers from data. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

**F.24.3.8. Options for PGP Functions**

Options are named to be similar to GnuPG. An option’s value should be given after an equal sign; separate options from each other with commas. For example:

pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
Appendix F. Additional Supplied Modules

All of the options except convert-crlf apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably compress-algo and unicode-mode. The rest should have reasonable defaults.

F.24.3.8.1. cipher-algo
Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)
Default: aes128
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.24.3.8.2. compress-algo
Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:
0 - no compression
1 - ZIP compression
2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.24.3.8.3. compress-level
How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.24.3.8.4. convert-crlf
Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt
F.24.3.8.5. disable-mdc
Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.24.3.8.6. sess-key
Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.24.3.8.7. s2k-mode
Which S2K algorithm to use.

Values:
  0 - Without salt. Dangerous!
  1 - With salt but with fixed iteration count.
  3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.24.3.8.8. s2k-digest-algo
Which digest algorithm to use in S2K calculation.

Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.24.3.8.9. s2k-cipher-algo
Which cipher to use for encrypting separate session key.

Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt
F.24.3.8.10. \textit{unicode-mode}

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1  
Default: 0  
Applies to: pgp\_sym\_encrypt, pgp\_pub\_encrypt

F.24.3.9. \textbf{Generating PGP Keys with GnuPG}

To generate a new key:

\texttt{gpg --gen-key}

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with \texttt{gpg --edit-key}.

To list keys:

\texttt{gpg --list-secret-keys}

To export a public key in ASCII-armor format:

\texttt{gpg -a --export KEYID > public.key}

To export a secret key in ASCII-armor format:

\texttt{gpg -a --export-secret-keys KEYID > secret.key}

You need to use \texttt{dearmor()} on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop \texttt{-a} from the command.

For more details see \texttt{man gpg}, The GNU Privacy Handbook\textsuperscript{3} and other documentation on http://www.gnupg.org.

F.24.3.10. \textbf{Limitations of PGP Code}

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.

\textsuperscript{3} http://www.gnupg.org/gph/en/manual.html
• No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
• No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with pgcrypto, but create new ones, as the usage scenario is rather different.

F.24.4. Raw Encryption Functions

These functions only run a cipher over data; they don’t have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don’t provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don’t handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea

encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea

Encrypt/decrypt data using the cipher method specified by type. The syntax of the type string is:

algorithm [ - mode ] [ /pad: padding ]

where algorithm is one of:

• bf — Blowfish
• aes — AES (Rijndael-128, 192 or 256)

and mode is one of:

• cbc — next block depends on previous (default)
• ecb — each block is encrypted separately (for testing only)

and padding is one of:

• pkcs — data may be any length (default)
• none — data must be multiple of cipher block size

So, for example, these are equivalent:
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')

In encrypt\_iv and decrypt\_iv, the iv parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

**F.24.5. Random-Data Functions**

gen\_random\_bytes(count integer) returns bytea

Returns count cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

gen\_random\_uuid() returns uuid

Returns a version 4 (random) UUID.

**F.24.6. Notes**

**F.24.6.1. Configuration**

gpcrypto configures itself according to the findings of the main PostgreSQL configure script. The options that affect it are --with-zlib and --with-openssl.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

**Table F-20. Summary of Functionality with and without OpenSSL**

<table>

</table>
Appendix F. Additional Supplied Modules

Notes:

1. SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, `pgcrypto` will use built-in code.
2. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
3. AES is included in OpenSSL since version 0.9.7. For older versions, `pgcrypto` will use built-in code.

F.24.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.24.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks\(^\text{4}\). For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.25. pg_freespacemap

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default public access is revoked from the functions, just in case there are security issues lurking.
F.25.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They’re rounded to precision of 1/256th of BLCKSZ (32 bytes with default BLCKSZ), and they’re not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

Note: The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

F.25.2. Sample Output

postgres=# SELECT * FROM pg_freespace('foo');

| blkno | avail |
|-------+-------|
| 0     | 0     |
| 1     | 0     |
| 2     | 0     |
| 3     | 32    |
| 4     | 704   |
| 5     | 704   |
| 6     | 704   |
| 7     | 1216  |
| 8     | 704   |
| 9     | 704   |
| 10    | 704   |
| 11    | 704   |
| 12    | 704   |
| 13    | 704   |
| 14    | 704   |
| 15    | 704   |
| 16    | 704   |
| 17    | 704   |
| 18    | 704   |
| 19    | 3648  |

(20 rows)

postgres=# SELECT * FROM pg_freespace('foo', 7);

pg_freespace

F.26. pg_prewarm

The pg_prewarm module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache.

F.26.1. Functions

pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
  first_block int8 default null,
  last_block int8 default null) RETURNS int8

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually main. The fourth argument is the first block number to prewarm (NULL is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (NULL means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. prefetch issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. read reads the requested range of blocks; unlike prefetch, this is synchronous and supported on all platforms and builds, but may be slower. buffer reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using prefetch or read, or by PostgreSQL when using buffer — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

F.26.2. Author

Robert Haas <rhaas@postgresql.org>
F.27. pgrowlocks

The pgrowlocks module provides a function to show row locking information for a specified table.

F.27.1. Overview

pgrowlocks(text) returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F-21.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransaction)</td>
</tr>
</tbody>
</table>

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If the table as a whole is exclusive-locked by someone else, pgrowlocks will be blocked.
2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.
Appendix F. Additional Supplied Modules

F.27.2. Sample Output

```sql
=# SELECT * FROM pgrowlocks('t1');

<table>
<thead>
<tr>
<th>locked_row</th>
<th>locker</th>
<th>multi</th>
<th>xids</th>
<th>modes</th>
<th>pids</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0,1)</td>
<td>609</td>
<td>f</td>
<td>{609}</td>
<td>&quot;For Share&quot;</td>
<td>{3161}</td>
</tr>
<tr>
<td>(0,2)</td>
<td>609</td>
<td>f</td>
<td>{609}</td>
<td>&quot;For Share&quot;</td>
<td>{3161}</td>
</tr>
<tr>
<td>(0,3)</td>
<td>607</td>
<td>f</td>
<td>{607}</td>
<td>&quot;For Update&quot;</td>
<td>{3107}</td>
</tr>
<tr>
<td>(0,4)</td>
<td>607</td>
<td>f</td>
<td>{607}</td>
<td>&quot;For Update&quot;</td>
<td>{3107}</td>
</tr>
</tbody>
</table>

(4 rows)
```

F.27.3. Author

Tatsuo Ishii

F.28. `pg_stat_statements`

The `pg_stat_statements` module provides a means for tracking execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `pg_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

F.28.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F-22.

<table>

<td>Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)</td>
</tr>
</tbody>
</table>

For security reasons, non-superusers are not allowed to see the SQL text or queryid of queries executed by other users. They can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, SELECT, INSERT, UPDATE, and DELETE) are combined into a single pg_stat_statements entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant’s value has been ignored for purposes of matching the query to other queries, the constant is replaced by ? in the pg_stat_statements display. The rest of the query text is that of the first query that had the particular queryid hash value associated with the pg_stat_statements entry.

In some cases, queries with visibly different texts might get merged into a single pg_stat_statements entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the queryid hash value is computed on the post-parse-analysis representation of the queries, the
opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different search_path settings.

Consumers of pg_stat_statements may wish to use queryid (perhaps in combination with dbid and userid) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the queryid hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, pg_stat_statements will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that queryid will be stable across major versions of PostgreSQL.

As a rule of thumb, queryid values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical queryid values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so queryid will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, pg_stat_statements may choose to discard the query texts, whereupon all existing entries in the pg_stat_statements view will show null query fields, though the statistics associated with each queryid are preserved. If this happens, consider reducing pg_stat_statements.max to prevent recurrences.

F.28.2. Functions

pg_stat_statements_reset() returns void

pg_stat_statements_reset discards all statistics gathered so far by pg_stat_statements. By default, this function can only be executed by superusers.

pg_stat_statements(showtext boolean) returns setof record

The pg_stat_statements view is defined in terms of a function also named pg_stat_statements. It is possible for clients to call the pg_stat_statements function directly, and by specifying showtext := false have query text be omitted (that is, the OUT argument that corresponds to the view’s query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all pg_stat_statements itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the pg_stat_statements data.
F.28.3. Configuration Parameters

pg_stat_statements.max (integer)

pg_stat_statements.max is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the pg_stat_statements view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

pg_stat_statements.track (enum)

pg_stat_statements.track controls which statements are counted by the module. Specify top to track top-level statements (those issued directly by clients), all to also track nested statements (such as statements invoked within functions), or none to disable statement statistics collection. The default value is top. Only superusers can change this setting.

pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE. The default value is on. Only superusers can change this setting.

pg_stat_statements.save (boolean)

pg_stat_statements.save specifies whether to save statement statistics across server shutdowns. If it is off then statistics are not saved at shutdown nor reloaded at server start. The default value is on. This parameter can only be set in the postgresql.conf file or on the server command line.

The module requires additional shared memory proportional to pg_stat_statements.max. Note that this memory is consumed whenever the module is loaded, even if pg_stat_statements.track is set to none.

These parameters must be set in postgresql.conf. Typical usage might be:

# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

pg_stat_statements.max = 10000
pg_stat_statements.track = all

F.28.4. Sample Output

bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_time, rows, 100.0 * shared_blks_hit / nullif(shared_blks_hit + shared_blks_read, 0) AS hit_percent

F.29. pgstattuple
The pgstattuple module provides various functions to obtain tuple-level statistics.

F.29.1. Functions
Appendix F. Additional Supplied Modules

pgstattuple(regclass) returns record

pgstattuple returns a relation's physical length, percentage of "dead" tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[
   RECORD 1 ]--------
   table_len   | 458752
   tuple_count | 1470
   tuple_len   | 438896
   tuple_percent | 95.67
   dead_tuple_count | 11
   dead_tuple_len | 3157
   dead_tuple_percent | 0.69
   free_space   | 8932
   free_percent | 1.95

The output columns are described in Table F-23.

Table F-23. pgstattuple Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

Note: The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

pgstattuple acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

pgstattuple judges a tuple is "dead" if HeapTupleSatisfiesDirty returns false.

pgstattuple(text) returns record

This is the same as pgstattuple(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.
pgstatindex(regclass) returns record

pgstatindex returns a record showing information about a B-tree index. For example:

test=> SELECT * FROM pgstatindex('pg_cast_oid_index');

<table>
<thead>
<tr>
<th>RECORD 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
</tr>
<tr>
<td>tree_level</td>
</tr>
<tr>
<td>index_size</td>
</tr>
<tr>
<td>root_block_no</td>
</tr>
<tr>
<td>internal_pages</td>
</tr>
<tr>
<td>leaf_pages</td>
</tr>
<tr>
<td>empty_pages</td>
</tr>
<tr>
<td>deleted_pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
</tr>
</tbody>
</table>

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported index_size will normally correspond to one more page than is accounted for by internal_pages + leaf_pages + empty_pages + deleted_pages, because it also includes the index’s metapage.

As with pgstattuple, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

pgstatindex(text) returns record

This is the same as pgstatindex(regclass), except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstatginindex(regclass) returns record

pgstatginindex returns a record showing information about a GIN index. For example:

test=> SELECT * FROM pgstatginindex('test_gin_index');

<table>
<thead>
<tr>
<th>RECORD 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2523</td>
</tr>
</tbody>
</table>
version | 1
pending_pages | 0
pending_tuples | 0

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

pg_relpages(regclass) returns bigint

pg_relpages returns the number of pages in the relation.

pg_relpages(text) returns bigint

This is the same as pg_relpages(regclass), except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

pgstattuple_approx(regclass) returns record

pgstattuple_approx is a faster alternative to pgstattuple that returns approximate results. The argument is the target relation’s name or OID. For example:

test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
- [ RECORD 1 ]----------
  table_len | 573440
  scanned_percent | 2
  approx_tuple_count | 2740
  approx_tuple_len | 561210
  approx_tuple_percent | 97.87
  dead_tuple_count | 0
  dead_tuple_len | 0
  dead_tuple_percent | 0
  approx_free_space | 11996
  approx_free_percent | 2.09

The output columns are described in Table F-24.

Whereas pgstattuple always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, pgstattuple_approx tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live
Appendix F. Additional Supplied Modules

tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

Table F-24. pgstattuple_approx Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes (exact)</td>
</tr>
<tr>
<td>scanned_percent</td>
<td>float8</td>
<td>Percentage of table scanned</td>
</tr>
<tr>
<td>approx_tuple_count</td>
<td>bigint</td>
<td>Number of live tuples (estimated)</td>
</tr>
<tr>
<td>approx_tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes (estimated)</td>
</tr>
<tr>
<td>approx_tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples (exact)</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes (exact)</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>approx_free_space</td>
<td>bigint</td>
<td>Total free space in bytes (estimated)</td>
</tr>
<tr>
<td>approx_free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

In the above output, the free space figures may not match the pgstattuple output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.29.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.30. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

F.30.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.
Note: pg_trgm ignores non-word characters (non-alphanumeric) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is "c", "ca", "cat", and "at". The set of trigrams in the string "foo|bar" is "f", "fo", "foo", "oo", "b", "ba", "bar", and "ar".

F.30.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F-25, the operators in Table F-26.

Table F-25. pg_trgm Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity(text, text)</td>
<td>real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
<tr>
<td>show_trgm(text)</td>
<td>text[]</td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td>show_limit()</td>
<td>real</td>
<td>Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example.</td>
</tr>
<tr>
<td>set_limit(real)</td>
<td>real</td>
<td>Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in.</td>
</tr>
</tbody>
</table>

Table F-26. pg_trgm Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
</table>

2526
### F.30.3. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```sql
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```sql
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to `word`, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```sql
SELECT t, t <-'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text % text</code></td>
<td>boolean</td>
<td>Returns true if its arguments have a similarity that is greater than the current similarity threshold set by <code>set_limit</code>.</td>
</tr>
<tr>
<td><code>text &lt;-' text</code></td>
<td>real</td>
<td>Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.</td>
</tr>
</tbody>
</table>
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (~ and ~* operators), for example

SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both LIKE and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere. As a rule of thumb, a GIN index is faster to search than a GiST index, but slower to build or update; so GIN is better suited for static data and GiST for often-updated data.

### F.30.4. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```sql
CREATE TABLE words AS SELECT word FROM
  ts_stat('SELECT to_tsvector("simple", bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```sql
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note:** Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.31. postgres_fdw

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table’s, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, or DELETE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique index inference specification is omitted.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although
Appendix F. Additional Supplied Modules

postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting WHERE clauses slightly differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.31.1. FDW Options of postgres_fdw

F.31.1.1. Connection Options

A foreign server using the postgres_fdw foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 31.1.2, except that these options are not allowed:

- user and password (specify these in a user mapping, instead)
- client_encoding (this is automatically set from the local server encoding)
- fallback_application_name (always set to postgres_fdw)

Only superusers may connect to foreign servers without password authentication, so always specify the password option for user mappings belonging to non-superusers.

F.31.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table’s names.

schema_name

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table’s schema is used.

table_name

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table’s name is used.

column_name

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column’s name is used.

F.31.1.3. Cost Estimation Options

postgres_fdw retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional
remote query to get a cost estimate. So postgres_fdw provides the following options to control how cost estimation is done:

use_remote_estimate

This option, which can be specified for a foreign table or a foreign server, controls whether postgres_fdw issues remote EXPLAIN commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is false.

fdw_startup_cost

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

fdw_tuple_cost

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When use_remote_estimate is true, postgres_fdw obtains row count and cost estimates from the remote server and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. When use_remote_estimate is false, postgres_fdw performs local row count and cost estimation and then adds fdw_startup_cost and fdw_tuple_cost to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table’s statistics are available. Running ANALYZE on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.31.1.4. Updatability Options

By default all foreign tables using postgres_fdw are assumed to be updatable. This may be overridden using the following option:

updatable

This option controls whether postgres_fdw allows foreign tables to be modified using INSERT, UPDATE and DELETE commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is true.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the information_schema views will report a postgres_fdw foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.
F.31.1.5. Importing Options

postgres_fdw is able to import foreign table definitions using IMPORT FOREIGN SCHEMA. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the IMPORT FOREIGN SCHEMA command):

import_collate

This option controls whether column COLLATE options are included in the definitions of foreign tables imported from a foreign server. The default is true. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it’s running on a different operating system.

import_default

This option controls whether column DEFAULT expressions are included in the definitions of foreign tables imported from a foreign server. The default is false. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; nextval() is a common source of problems. The IMPORT will fail altogether if an imported default expression uses a function or operator that does not exist locally.

import_not_null

This option controls whether column NOT NULL constraints are included in the definitions of foreign tables imported from a foreign server. The default is true.

Note that constraints other than NOT NULL will never be imported from the remote tables. Although PostgreSQL does support CHECK constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a CHECK constraint could lead to hard-to-detect errors in query optimization. So if you wish to import CHECK constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of CHECK constraints on foreign tables, see CREATE FOREIGN TABLE.

F.31.2. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

F.31.3. Transaction Management

During a query that references any remote tables on a foreign server, postgres_fdw opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote
transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future PostgreSQL release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

### F.31.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only built-in data types, operators, and functions. Operators and functions in the clauses must be `IMMUTABLE` as well.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

### F.31.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see CREATE FUNCTION) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for the parameters `TimeZone`, `DateStyle`, `IntervalStyle`, and `extra_float_digits`. These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is not recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

### F.31.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable
Appendix F. Additional Supplied Modules

built-in functions and operators are safe to send to the remote server for execution, if they appear in a WHERE clause for a foreign table. Thus, a built-in function that was added since the remote server’s release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with OFFSET 0 as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.31.7. Examples

Here is an example of creating a foreign table with postgres_fdw. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using CREATE SERVER. In this example we wish to connect to a PostgreSQL server on host 192.83.123.89 listening on port 5432. The database to which the connection is made is named foreign_db on the remote server:

```
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with CREATE USER MAPPING, is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with CREATE FOREIGN TABLE. In this example we wish to access the table named some_schema.some_table on the remote server. The local name for it will be foreign_table:

```
CREATE FOREIGN TABLE foreign_table (id integer NOT NULL,
                                      data text)
SERVER foreign_server
OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It’s essential that the data types and other properties of the columns declared in CREATE FOREIGN TABLE match the actual remote table. Column names must match as well, unless you attach column_name options to the individual columns to show how they are named in the remote table. In many cases, use of IMPORT FOREIGN SCHEMA is preferable to constructing foreign table definitions manually.
F.31.8. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.32. seg

This module implements a data type seg for representing line segments, or floating point intervals. seg can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

F.32.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
   pH
  ---
   6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50':seg as "pH";
   pH
---------
   6.25 .. 6.50
(1 row)
```
F.32.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (.. or ...). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (<, > or ~) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F-27 gives an overview of allowed representations; Table F-28 shows some examples.

In Table F-27, $x$, $y$, and $delta$ denote floating-point numbers. $x$ and $y$, but not $delta$, can be preceded by a certainty indicator.

**Table F-27. seg External Representations**

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x$</td>
<td>Single value (zero-length interval)</td>
</tr>
<tr>
<td>$x$ .. $y$</td>
<td>Interval from $x$ to $y$</td>
</tr>
<tr>
<td>$x$ (+-) $delta$</td>
<td>Interval from $x - delta$ to $x + delta$</td>
</tr>
<tr>
<td>$x$ ..</td>
<td>Open interval with lower bound $x$</td>
</tr>
<tr>
<td>.. $x$</td>
<td>Open interval with upper bound $x$</td>
</tr>
</tbody>
</table>

**Table F-28. Examples of Valid seg Input**

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>Creates a zero-length segment (a point, if you will)</td>
</tr>
<tr>
<td>~5.0</td>
<td>Creates a zero-length segment and records ~ in the data. ~ is ignored by seg operations, but is preserved as a comment.</td>
</tr>
<tr>
<td>&lt;5.0</td>
<td>Creates a point at 5.0. &lt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>&gt;5.0</td>
<td>Creates a point at 5.0. &gt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>5(+-)0.3</td>
<td>Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn’t preserved.</td>
</tr>
<tr>
<td>50 ..</td>
<td>Everything that is greater than or equal to 50</td>
</tr>
<tr>
<td>.. 0</td>
<td>Everything that is less than or equal to 0</td>
</tr>
<tr>
<td>1.5e-2 .. 2E-2</td>
<td>Creates an interval 0.015 .. 0.02</td>
</tr>
<tr>
<td>1 ... 2</td>
<td>The same as 1..2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)</td>
</tr>
</tbody>
</table>

Because .. is widely used in data sources, it is allowed as an alternative spelling of ... Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0 .. 23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in seg input.

As a sanity check, seg rejects intervals with the lower bound greater than the upper, for example 5 .. 2.
**F.32.3. Precision**

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

**F.32.4. Usage**

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in Table F-29.

**Table F-29. Seg GiST Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[a, b] &lt; [c, d]</code></td>
<td><code>[a, b]</code> is entirely to the left of <code>[c, d]</code>. That is, <code>[a, b]</code> is true if <code>b &lt; c</code> and false otherwise.</td>
</tr>
<tr>
<td><code>[a, b] &gt; [c, d]</code></td>
<td><code>[a, b]</code> is entirely to the right of <code>[c, d]</code>. That is, <code>[a, b]</code> is true if <code>a &gt; d</code> and false otherwise.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&lt; [c, d]</code></td>
<td>Overlaps or is left of — This might be better read as “does not extend to right of”. It is true when <code>b &lt;= d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&gt; [c, d]</code></td>
<td>Overlaps or is right of — This might be better read as “does not extend to left of”. It is true when <code>a &gt;= c</code>.</td>
</tr>
<tr>
<td><code>[a, b] = [c, d]</code></td>
<td>Same as — The segments <code>[a, b]</code> and <code>[c, d]</code> are identical, that is, <code>a = c</code> and <code>b = d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &amp;&amp; [c, d]</code></td>
<td>The segments <code>[a, b]</code> and <code>[c, d]</code> overlap.</td>
</tr>
<tr>
<td><code>[a, b] @&gt; [c, d]</code></td>
<td>The segment <code>[a, b]</code> contains the segment <code>[c, d]</code>, that is, <code>a &lt;= c</code> and <code>b &gt;= d</code>.</td>
</tr>
<tr>
<td><code>[a, b] &lt;@ [c, d]</code></td>
<td>The segment <code>[a, b]</code> is contained in <code>[c, d]</code>, that is, <code>a &gt;= c</code> and <code>b &lt;= d</code>.</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[a, b] &lt; [c, d]</code></td>
<td>Less than</td>
</tr>
<tr>
<td><code>[a, b] &gt; [c, d]</code></td>
<td>Greater than</td>
</tr>
</tbody>
</table>
These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

### F.32.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn’t completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
    seg
----------
   9.0 .. 11 -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

### F.32.6. Credits

Original author: Gene Selkov, Jr. &lt;selkovjr@mcs.anl.gov&gt;, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

### F.33. sepgsql

sepgsql is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.

#### Warning

The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.33.7.
F.33.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as `system_u:object_r:sepgsql_table_t:s0`. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The SECURITY LABEL statement allows assignment of a security label to a database object.

F.33.2. Installation

`sepgsql` can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need `libselinux` 2.1.10 or higher and `selinux-policy` 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The `sestatus` command allows you to check the status of SELinux. A typical display is:

```
$ sestatus
SELinux status: enabled
SELinuxfs mount: /selinux
Current mode: enforcing
Mode from config file: enforcing
Policy version: 24
Policy from config file: targeted
```

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option `--with-selinux` in your PostgreSQL configure command. Be sure that the `libselinux-devel` RPM is installed at build time.

To use this module, you must include `sepgsql` in the `shared_preload_libraries` parameter in `postgresql.conf`. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute `sepgsql.sql` in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with `sepgsql` functions and security labels installed. Adjust the paths shown as appropriate for your installation:

```
$ export PGDATA=/path/to/data/directory
$ initdb
$ vi $PGDATA/postgresql.conf
    change #shared_preload_libraries = "
    to
      # (change requires restart)
```
shared_preload_libraries = 'sepgsql'  # (change requires restart)

$ for DBNAME in template0 template1 postgres; do
    postgres --single -F -c exit_on_error=true $DBNAME \
        < /usr/local/pgsql/share/contrib/sepgsql.sql > /dev/null
done

Please note that you may see some or all of the following notifications depending on the particular versions you have of libselinux and selinux-policy:

/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type db_language

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.33.3. Regression Tests

Due to the nature of SELinux, running the regression tests for sepgsql requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary make check or make installcheck command; you must set up the configuration and then invoke the test script manually. The tests must be run in the contrib/sepgsql directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to make installcheck not make check.

First, set up sepgsql in a working database according to the instructions in Section F.33.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The sepgsql-regtest policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file sepgsql-regtest.te, which is done using make with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. Once built, install this policy package using the semodule command, which loads supplied policy packages into the kernel. If the package is correctly installed, semodule -l should list sepgsql-regtest as an available policy package:

$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07

Third, turn on sepgsql_regression_test_mode. For security reasons, the rules in sepgsql-regtest are not enabled by default; the sepgsql_regression_test_mode parameter enables the rules needed to launch the regression tests. It can be turned on using the setsebool command:

$ setsebool -P sepgsql_regression_test_mode true

2540
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on

Fourth, verify your shell is operating in the unconfined_t domain:

$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023

See Section F.33.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

$ ./test_sepgsql

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the sepgsql module.

After completing the tests, it’s recommended you disable the sepgsql_regression_test_mode parameter:

$ sudo setsebool sepgsql_regression_test_mode off

You might prefer to remove the sepgsql-regtest policy entirely:

$ sudo semodule -r sepgsql-regtest

**F.33.4. GUC Parameters**

**sepgsql.permissive (boolean)**

This parameter enables sepgsql to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the postgresql.conf file or on the server command line.

When this parameter is on, sepgsql functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

**sepgsql.debug_audit (boolean)**

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.
F.33.5. Features

F.33.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label unlabeled_t.

Currently, sepgsql allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When sepgsql is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator’s label, the label assigned to the new object’s parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

F.33.5.2. DML Permissions

For tables, \texttt{db\_table:select}, \texttt{db\_table:insert}, \texttt{db\_table:update} or \texttt{db\_table:delete} are checked for all the referenced target tables depending on the kind of statement; in addition, \texttt{db\_table:select} is also checked for all the tables that contain columns referenced in the \texttt{WHERE} or \texttt{RETURNING} clause, as a data source for \texttt{UPDATE}, and so on.

Column-level permissions will also be checked for each referenced column. \texttt{db\_column:select} is checked on not only the columns being read using \texttt{SELECT}, but those being referenced in other DML statements; \texttt{db\_column:update} or \texttt{db\_column:insert} will also be checked for columns being modified by \texttt{UPDATE} or \texttt{INSERT}.

For example, consider:

\begin{verbatim}
UPDATE t1 SET x = 2, y = md5sum(y) WHERE z = 100;
\end{verbatim}

Here, \texttt{db\_column:select} will be checked for \texttt{t1.x}, since it is being updated, \texttt{db\_column:{select update}} will be checked for \texttt{t1.y}, since it is both updated and referenced, and \texttt{db\_column:select} will be checked for \texttt{t1.z}, since it is only referenced. \texttt{db\_table:{select update}} will also be checked at the table level.

For sequences, \texttt{db\_sequence:get\_value} is checked when we reference a sequence object using \texttt{SELECT} however, note that we do not currently check permissions on execution of corresponding functions such as \texttt{lastval()}.

For views, \texttt{db\_view:expand} will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, \texttt{db\_procedure:{execute}} will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks \texttt{db\_procedure:{entrypoint}} permission to check whether it can perform as entry point of trusted procedure.
In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when `sepgsql` is enabled.

### F.33.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires `create` permission. SELinux will grant or deny this permission based on the client’s security label and the proposed security label for the new object. In some cases, additional privileges are required:

- **CREATE DATABASE** additionally requires `getattr` permission for the source or template database.
- Creating a schema object additionally requires `add_name` permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as `LEAKPROOF` additionally requires `install` permission. (This permission is also checked when `LEAKPROOF` is set for an existing function.)

When `DROP` command is executed, `drop` will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via `CASCADE`. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires `remove_name` on the schema.

When `ALTER` command is executed, `setattr` will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires `remove_name` permission on the old schema and `add_name` permission on the new one.
- Setting the `LEAKPROOF` attribute on a function requires `install` permission.
- Using `SECURITY LABEL` on an object additionally requires `relabelfrom` permission for the object in conjunction with its old security label and `relabelto` permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only `setattr` should be checked here. This is currently not done due to implementation restrictions.)
F.33.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g., rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```sql
postgres=# CREATE TABLE customer (
    cid int primary key,
    cname text,
    credit text
);
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit IS 'system_u:object_r:sepgsql_secret_table_t:s0';
SECURITY LABEL
postgres=# CREATE FUNCTION show_credit(int) RETURNS text
    AS 'SELECT regexp_replace(credit, "-\[0-9\]+\$", "-xxxx", "g")
    FROM customer WHERE cid = $1'
    LANGUAGE sql;
CREATE FUNCTION
postgres=# SECURITY LABEL ON FUNCTION show_credit(int)
    IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';
SECURITY LABEL
```

The above operations should be performed by an administrative user.

```sql
postgres=# SELECT * FROM customer;
ERROR: SELinux: security policy violation
postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
cid | cname | show_credit
-----+--------+---------------------
1 | taro | 1111-2222-3333-xxxx
2 | hanako | 5555-6666-7777-xxxx
(2 rows)
```

In this case, a regular user cannot reference `customer.credit` directly, but a trusted procedure `show_credit` allows him to print the credit card numbers of customers with some of the digits masked out.

F.33.5.5. Dynamic Domain Transitions

It is possible to use SELinux’s dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the `setcurrent` permission and also `dyntransition` from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the `dyntransition` permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:
regression=# select sepgsql_getcon();

sepgsql_getcon

-------------------------------------------------------
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4');

sepgsql_setcon

----------------
t
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c1023');

ERROR: SELinux: security policy violation

In this example above we were allowed to switch from the larger MCS range \texttt{c1.c1023} to the smaller range \texttt{c1.c4}, but switching back was denied.

A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the \texttt{sepgsql_setcon()} function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using \texttt{sepgsql_setcon()} with \texttt{NULL} argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

\textbf{F.33.5.6. Miscellaneous}

We reject the LOAD command across the board, because any module loaded could easily circumvent security policy enforcement.

\textbf{F.33.6. Sepgsql Functions}

Table F-30 shows the available functions.

<table>
<thead>
<tr>
<th>sepgsql_getcon() returns text</th>
<th>Returns the client domain, the current security label of the client.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sepgsql_setcon(text) returns bool</td>
<td>Switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts \texttt{NULL} input as a request to transition to the client’s original domain.</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sepgsql_mcstrans_in(text)</td>
<td>Translates the given qualified MLS/MCS range into raw format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_mcstrans_out(text)</td>
<td>Translates the given raw MLS/MCS range into qualified format if the mcstrans daemon is running.</td>
</tr>
<tr>
<td>sepgsql_restorecon(text)</td>
<td>Sets up initial security labels for all objects within the current database. The argument may be NULL, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

F.33.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.

Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

PostgreSQL supports row-level access, but sepgsql does not.

Covert channels

sepgsql does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

This document provides a wide spectrum of knowledge to administer SELinux on your systems. It focuses primarily on Fedora, but is not limited to Fedora.

This document answers frequently asked questions about SELinux. It focuses primarily on Fedora, but is not limited to Fedora.

F.33.9. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.34. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.34.1. refint — Functions for Implementing Referential Integrity

check_primary_key() and check_foreign_key() are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

check_primary_key() checks the referencing table. To use, create a BEFORE INSERT OR UPDATE trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table’s column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

check_foreign_key() checks the referenced table. To use, create a BEFORE DELETE OR UPDATE trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (cascade — to delete the referencing row, restrict — to abort transaction if referencing keys exist, setnull — to set referencing key fields to null), the triggered table’s column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in refint.example.

7. http://docs.fedoraproject.org/selinux-faq
F.34.2. timetravel — Functions for Implementing Time Travel

Long ago, PostgreSQL had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of \texttt{abstime} type to store the date when a tuple was inserted (\texttt{start\_date}) and changed/deleted (\texttt{stop\_date}):

\begin{verbatim}
CREATE TABLE mytab ( ...
    start_date abstime,
    stop_date abstime
    ...
);
\end{verbatim}

The columns can be named whatever you like, but in this discussion we’ll call them \texttt{start\_date} and \texttt{stop\_date}.

When a new row is inserted, \texttt{start\_date} should normally be set to current time, and \texttt{stop\_date} to \texttt{infinity}. The trigger will automatically substitute these values if the inserted data contains nulls in these columns. Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with \texttt{stop\_date} equal to \texttt{infinity} are “valid now”, and can be modified. Tuples with a finite \texttt{stop\_date} cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the \texttt{stop\_date} in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. \texttt{Start\_date} in this new tuple will be set to current time and \texttt{stop\_date} to \texttt{infinity}.

A delete does not actually remove the tuple but only sets its \texttt{stop\_date} to current time.

To query for tuples “valid now”, include \texttt{stop\_date = ‘infinity’} in the query’s WHERE condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on \texttt{start\_date} and \texttt{stop\_date}.

\texttt{timetravel()} is the general trigger function that supports this behavior. Create a \texttt{BEFORE INSERT OR UPDATE OR DELETE} trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the \texttt{start\_date} and \texttt{stop\_date} columns. Optionally, you can specify one to three more arguments, which must refer to columns of type \texttt{text}. The trigger will store the name of the current user into the first of these columns during INSERT, the second column during UPDATE, and the third during DELETE.

\texttt{set_timetravel()} allows you to turn time-travel on or off for a table. \texttt{set_timetravel(‘mytab’, 1)} will turn TT ON for table \texttt{mytab}. \texttt{set_timetravel(‘mytab’, 0)} will turn TT OFF for table \texttt{mytab}. In both cases the old status is reported. While TT is off, you can modify the \texttt{start\_date} and \texttt{stop\_date} columns freely. Note that the on/off status is local to the current database session — fresh sessions will always start out with TT ON for all tables.

\texttt{get_timetravel()} returns the TT state for a table without changing it.

There is an example in \texttt{timetravel.example}. 

\newpage
F.34.3. autoinc — Functions for Autoincrementing Fields

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

F.34.4. insert_username — Functions for Tracking Who Changed a Table

insert_username() is a trigger that stores the current user’s name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

F.34.5. moddatetime — Functions for Tracking Last Modification Time

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.

F.35. sslinfo

The sslinfo module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return NULL) if the current connection does not use SSL.

This extension won’t build at all unless the installation was configured with --with-openssl.
F.35.1. Functions Provided

ssl_is_used() returns boolean

Returns TRUE if current connection to server uses SSL, and FALSE otherwise.

ssl_version() returns text

Returns the name of the protocol used for the SSL connection (e.g. SSLv2, SSLv3, or TLSv1).

ssl_cipher() returns text

Returns the name of the cipher used for the SSL connection (e.g. DHE-RSA-AES256-SHA).

ssl_client_cert_present() returns boolean

Returns TRUE if current client has presented a valid SSL client certificate to the server, and FALSE otherwise. (The server might or might not be configured to require a client certificate.)

ssl_client_serial() returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change his keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

ssl_client_dn() returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like /CN=Somebody /C=Some country/O=Some organization.

ssl_issuer_dn() returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for ssl_client_dn.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server’s root.crt file, or if this CA has issued some intermediate certificate authority certificates.

ssl_client_dn_field(fieldname text) returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
Appendix F. Additional Supplied Modules

organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
eemailAddress

All of these fields are optional, except commonName. It depends entirely on your CA’s policy which of them would be included and which wouldn’t. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

ssl_issuer_field (fieldname text) returns text

Same as ssl_client_dn_field, but for the certificate issuer rather than the certificate subject.

<td>setof record</td>
<td>Produces a “pivot table” containing row names plus ( N ) value columns, where ( N ) is determined by the row type specified in the calling query</td>
</tr>
<tr>
<td>crosstabN(text sql)</td>
<td>setof table_crosstab_N</td>
<td>Produces a “pivot table” containing row names plus ( N ) value columns. ( \text{crosstab2, crosstab3, and crosstab4} ) are predefined, but you can create additional ( \text{crosstabN} ) functions as described below</td>
</tr>
<tr>
<td>crosstab(text source_sql, text category_sql)</td>
<td>setof record</td>
<td>Produces a “pivot table” with the value columns specified by a second query</td>
</tr>
<tr>
<td>crosstab(text sql, int N)</td>
<td>setof record</td>
<td>Obsolete version of ( \text{crosstab(text)} ). The parameter ( N ) is now ignored, since the number of value columns is always determined by the calling query</td>
</tr>
<tr>
<td>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])</td>
<td>setof record</td>
<td>Produces a representation of a hierarchical tree structure</td>
</tr>
</tbody>
</table>

**F.36.1.1. normal_rand**

\( \text{normal_rand(int numvals, float8 mean, float8 stddev)} \) returns setof float8

\( \text{normal_rand} \) produces a set of normally distributed random values (Gaussian distribution).

\( \text{numvals} \) is the number of values to be returned from the function. \( \text{mean} \) is the mean of the normal distribution of values and \( \text{stddev} \) is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```sql
test=# SELECT * FROM normal_rand(1000, 5, 3);

normal_rand
----------------------
1.56556322244898
9.10040991424657
5.36957140345079
-0.369151492880995
0.283600703686639
```

2552
Appendix F. Additional Supplied Modules

4.82992125404908
9.71308014517282
2.49639286969028
(1000 rows)

F.36.1.2. crosstab(text)

crosstab(text sql)
crosstab(text sql, int N)

The crosstab function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

row1 val11
row1 val12
row1 val13
...
row2 val21
row2 val22
row2 val23
...

which we wish to display like

row1 val11 val12 val13 ...
row2 val21 val22 val23 ...
...

The crosstab function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The sql parameter is a SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. N is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

<table>
<thead>
<tr>
<th>row_name</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>cat3</td>
<td>val3</td>
</tr>
<tr>
<td>row1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>cat1</td>
<td>val5</td>
</tr>
<tr>
<td>row2</td>
<td>cat2</td>
<td>val6</td>
</tr>
<tr>
<td>row2</td>
<td>cat3</td>
<td>val7</td>
</tr>
<tr>
<td>row2</td>
<td>cat4</td>
<td>val8</td>
</tr>
</tbody>
</table>
The `crosstab` function is declared to return a set of record, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
row_name | category_1 | category_2
----------+------------+------------
row1      | val1       | val2
row2      | val5       | val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by N `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it’s just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(  
  'select rowid, attribute, value  
  from ct  
  where attribute = "att2" or attribute = "att3"  
  order by 1,2')  
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

row_name | category_1 | category_2 | category_3
----------+------------+------------+------------
test1     | val2       | val3
```
You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

### F.36.1.3. crosstabN (text)

The `crosstabN` functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```sql
CREATE TYPE tablefunc_crosstab_N AS {
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    ...
    category_N TEXT
};
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general crosstab function.

For instance, the example given in the previous section would also work as

```sql
SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = "att2" or attribute = "att3"
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying crosstab C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```sql
CREATE TYPE my_crosstab_float8_5_cols AS (}
```
Appendix F. Additional Supplied Modules

my_row_name text,
my_category_1 float8,
my_category_2 float8,
my_category_3 float8,
my_category_4 float8,
my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
RETURNS setof my_crosstab_float8_5_cols
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

- Use OUT parameters to define the return type implicitly. The same example could also be done this way:

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
IN text,
OUT my_row_name text,
OUT my_category_1 float8,
OUT my_category_2 float8,
OUT my_category_3 float8,
OUT my_category_4 float8,
OUT my_category_5 float8)
RETURNS setof record
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

F.36.1.4. crosstab(text, text)

crosstab(text source_sql, text category_sql)

The main limitation of the single-parameter form of crosstab is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn’t work well. The two-parameter form of crosstab handles this case by providing an explicit list of the categories corresponding to the output columns.

source_sql is a SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. It may also have one or more “extra” columns. The row_name column must be first. The category and value columns must be the last two columns, in that order. Any columns between row_name and category are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same row_name value.

For example, source_sql might produce a set something like:

SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;

<table>
<thead>
<tr>
<th>row_name</th>
<th>extra_col</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat1</td>
<td>val5</td>
</tr>
</tbody>
</table>
category_sql is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. category_sql might be something like:

```sql
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
</tr>
<tr>
<td>cat2</td>
</tr>
<tr>
<td>cat3</td>
</tr>
<tr>
<td>cat4</td>
</tr>
</tbody>
</table>

The crosstab function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

```sql
SELECT * FROM crosstab('...', '...')
    AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

<table>
<thead>
<tr>
<th>&lt;= value columns =&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_name</td>
</tr>
<tr>
<td>----------</td>
</tr>
<tr>
<td>row1</td>
</tr>
<tr>
<td>row2</td>
</tr>
</tbody>
</table>

The FROM clause must define the proper number of output columns of the proper data types. If there are \( N \) columns in the source_sql query’s result, the first \( N-2 \) of them must match up with the first \( N-2 \) output columns. The remaining output columns must have the type of the last column of the source_sql query’s result, and there must be exactly as many of them as there are rows in the category_sql query’s result.

The crosstab function produces one output row for each consecutive group of input rows with the same row_name value. The output row_name column, plus any “extra” columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching category values. If a row’s category does not match any output of the category_sql query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the source_sql query should always specify ORDER BY 1 to ensure that values with the same row_name are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the category_sql query’s output matches the specified output column order.
Here are two complete examples:

```sql
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
    'select year, month, qty from sales order by 1',
    'select m from generate_series(1,12) m'
) as (
    year int,
    "Jan" int,
    "Feb" int,
    "Mar" int,
    "Apr" int,
    "May" int,
    "Jun" int,
    "Jul" int,
    "Aug" int,
    "Sep" int,
    "Oct" int,
    "Nov" int,
    "Dec" int
);
```

<table>
<thead>
<tr>
<th>year</th>
<th>Jan</th>
<th>Feb</th>
<th>Mar</th>
<th>Apr</th>
<th>May</th>
<th>Jun</th>
<th>Jul</th>
<th>Aug</th>
<th>Sep</th>
<th>Oct</th>
<th>Nov</th>
<th>Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td>2007</td>
<td>1000</td>
<td>1500</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>500</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1500</td>
</tr>
<tr>
<td>2008</td>
<td>1000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>2000</td>
</tr>
</tbody>
</table>

(2 rows)

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
{
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
} AS
{
    rowid text,
    rowdt timestamp,
    temperature int4,
}
Appendix F. Additional Supplied Modules

```sql
test_result text,
test_startdate timestamp,
volts float8
);
```

| rowid | rowdt | temperature | test_result | test_startdate | volts |
|-------|--------------------------+-------------+-------------+--------------------------+--------|
| test1 | Sat Mar 01 00:00:00 2003 | 42 | PASS | | 2.6987 |
| test2 | Sun Mar 02 00:00:00 2003 | 53 | FAIL | Sat Mar 01 00:00:00 2003 | 3.1234 |

(2 rows)

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named crosstab_hash.

F.36.1.5. connectby

```sql
connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])
```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F-32 explains the parameters.

Table F-32. connectby Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>Name of the source relation</td>
</tr>
<tr>
<td>keyid_fld</td>
<td>Name of the key field</td>
</tr>
<tr>
<td>parent_keyid_fld</td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td>orderby_fld</td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
<tr>
<td>start_with</td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td>max_depth</td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td>branch_delim</td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the `start_with` value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```sql
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```
The first two output columns are used for the current row’s key and its parent row’s key; they must match the type of the table’s key field. The third output column is the depth in the tree and must be of type integer. If a branch_delim parameter was given, the next output column is the branch display and must be of type text. Finally, if an orderby_fld parameter was given, the last output column is a serial number, and must be of type integer.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified branch_delim string. If no branch display is wanted, omit both the branch_delim parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the orderby_fld parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if orderby_fld is specified.

The parameters representing table and field names are copied as-is into the SQL queries that connectby generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the branch_delim string not appear in any key values, else connectby may incorrectly report an infinite-recursion error. Note that if branch_delim is not provided, a default value of ~ is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
keyid | parent_keyid | level | branch
-------+--------------+-------+---------------------
row2 | | 0 | row2
row4 | row2 | 1 | row2~row4
row6 | row4 | 2 | row2~row4~row6
row8 | row6 | 3 | row2~row4~row6~row8
row5 | row2 | 1 | row2~row5
row9 | row5 | 2 | row2~row5~row9
(6 rows)
```

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
keyid | parent_keyid | level
-------+--------------+-------
2560
```
### Appendix F. Additional Supplied Modules

### F.36.2. Author

Joe Conway

---

### F.37. tcn

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an **AFTER trigger FOR EACH ROW.**
Appendix F. Additional Supplied Modules

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```sql
CREATE TABLE tcndata

CREATE TRIGGER tcndata_tcn_trigger

LISTEN

test=# insert into tcndata values (1, date '2012-12-22', 'one'),
    (1, date '2012-12-23', 'another'),
    (2, date '2012-12-23', 'two');

UPDATE tcndata set c = 'uno' where a = 1;

DELETE from tcndata where a = 1 and b = date '2012-12-22';
```

F.38. test_decoding

test_decoding is an example of a logical decoding output plugin. It doesn’t do anything especially useful, but can serve as a starting point for developing your own output plugin.

test_decoding receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:
### F.39. tsearch2

The tsearch2 module provides backwards-compatible text search functionality for applications that used tsearch2 before text searching was integrated into core PostgreSQL in release 8.3.

#### F.39.1. Portability Issues

Although the built-in text search features were based on tsearch2 and are largely similar to it, there are numerous small differences that will create portability issues for existing applications:

- Some functions’ names were changed, for example `rank` to `ts_rank`. The replacement tsearch2 module provides aliases having the old names.

- The built-in text search data types and functions all exist within the system schema `pg_catalog`. In an installation using tsearch2, these objects would usually have been in the `public` schema, though some users chose to place them in a separate schema of their own. Explicitly schema-qualified references to the objects will therefore fail in either case. The replacement tsearch2 module provides alias objects that are stored in `public` (or another schema if necessary) so that such references will still work.

- There is no concept of a “current parser” or “current dictionary” in the built-in text search features, only of a current search configuration (set by the `default_text_search_config` parameter). While the current parser and current dictionary were used only by functions intended for debugging, this might still pose a porting obstacle in some cases. The replacement tsearch2 module emulates these additional state variables and provides backwards-compatible functions for setting and retrieving them.

There are some issues that are not addressed by the replacement tsearch2 module, and will therefore require application code changes in any case:

- The old tsearch2 trigger function allowed items in its argument list to be names of functions to be invoked on the text data before it was converted to `tsvector` format. This was removed as being a security hole, since it was not possible to guarantee that the function invoked was the one intended. The recommended approach if the data must be massaged before being indexed is to write a custom trigger that does the work for itself.
Appendix F. Additional Supplied Modules

- Text search configuration information has been moved into core system catalogs that are noticeably different from the tables used by tsearch2. Any applications that examined or modified those tables will need adjustment.

- If an application used any custom text search configurations, those will need to be set up in the core catalogs using the new text search configuration SQL commands. The replacement tsearch2 module offers a little bit of support for this by making it possible to load an old set of tsearch2 configuration tables into PostgreSQL 8.3. (Without the module, it is not possible to load the configuration data because values in the regprocedure columns cannot be resolved to functions.) While those configuration tables won’t actually do anything, at least their contents will be available to be consulted while setting up an equivalent custom configuration in 8.3.

- The old reset_tsearch() and get_covers() functions are not supported.

- The replacement tsearch2 module does not define any alias operators, relying entirely on the built-in ones. This would only pose an issue if an application used explicitly schema-qualified operator names, which is very uncommon.

F.39.2. Converting a pre-8.3 Installation

The recommended way to update a pre-8.3 installation that uses tsearch2 is:

1. Make a dump from the old installation in the usual way, but be sure not to use -c (--clean) option of pg_dump or pg_dumpall.

2. In the new installation, create empty database(s) and install the replacement tsearch2 module into each database that will use text search. This must be done before loading the dump data! If your old installation had the tsearch2 objects in a schema other than public, be sure to adjust the CREATE EXTENSION command so that the replacement objects are created in that same schema.

3. Load the dump data. There will be quite a few errors reported due to failure to recreate the original tsearch2 objects. These errors can be ignored, but this means you cannot restore the dump in a single transaction (eg, you cannot use pg_restore’s -1 switch).

4. Examine the contents of the restored tsearch2 configuration tables (pg_ts_cfg and so on), and create equivalent built-in text search configurations as needed. You may drop the old configuration tables once you’ve extracted all the useful information from them.

5. Test your application.

At a later time you may wish to rename application references to the alias text search objects, so that you can eventually uninstall the replacement tsearch2 module.

F.39.3. References

Tsearch2 Development Site http://www.sai.msu.su/~megera/postgres/gist/tsearch/V2/
F.40. tsm_system_rows

The tsm_system_rows module provides the table sampling method SYSTEM_ROWS, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in SYSTEM sampling method, SYSTEM_ROWS performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

SYSTEM_ROWS does not support the REPEATABLE clause.

F.40.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_ROWS. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.41. tsm_system_time

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in SYSTEM sampling method, SYSTEM_TIME performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

SYSTEM_TIME does not support the REPEATABLE clause.

F.41.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_TIME. First install the extension:
CREATE EXTENSION tsm_system_time;

Then you can use it in a SELECT command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

### F.42. `unaccent`

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It’s a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

### F.42.1. Configuration

An `unaccent` dictionary accepts the following options:

- **RULES** is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

<table>
<thead>
<tr>
<th>Ace</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>À</td>
<td>A</td>
</tr>
<tr>
<td>Á</td>
<td>A</td>
</tr>
<tr>
<td>Å</td>
<td>A</td>
</tr>
<tr>
<td>Â</td>
<td>A</td>
</tr>
<tr>
<td>Æ</td>
<td>A</td>
</tr>
</tbody>
</table>

  The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
As with other PostgreSQL text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database’s encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in unaccent.rules, which is installed in $SHAREDIR/tsearch_data/ when the unaccent module is installed.

F.42.2. Usage

Installing the unaccent extension creates a text search template unaccent and a dictionary unaccent based on it. The unaccent dictionary has the default parameter setting RULES='unaccent', which makes it immediately usable with the standard unaccent.rules file. If you wish, you can alter the parameter, for example

mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');

or create new dictionaries based on the template.

To test the dictionary, you can try:

mydb=# select ts_lexize('unaccent','Hôtel');

hs_lexize
----------
{Hotel}
(1 row)

Here is an example showing how to insert the unaccent dictionary into a text search configuration:

mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
   ALTER MAPPING FOR hword, hword_part, word
   WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');

hs_tsvector
-----------
'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');

?column?
-------
t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));

hs_headline
-------------
<b>Hôtel</b> de la Mer
F.42.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it’s a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

\[
\text{unaccent}([\text{dictionary regdictionary}, ] \text{ string text}) \text{ returns text}
\]

If the `dictionary` argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```sql
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.43. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

F.43.1. uuid-oss Functions

Table F-33 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1()</code></td>
<td>This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
</tr>
</tbody>
</table>
### Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1mc()</code></td>
<td>This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
</tr>
<tr>
<td><code>uuid_generate_v3(namespace uuid, name text)</code></td>
<td>This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*()</code> functions shown in Table F-34. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <code>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</code> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</td>
</tr>
<tr>
<td><code>uuid_generate_v4()</code></td>
<td>This function generates a version 4 UUID, which is derived entirely from random numbers.</td>
</tr>
<tr>
<td><code>uuid_generate_v5(namespace uuid, name text)</code></td>
<td>This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.</td>
</tr>
</tbody>
</table>

#### Table F-34. Functions Returning UUID Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_nil()</code></td>
<td>A “nil” UUID constant, which does not occur as a real UUID.</td>
</tr>
<tr>
<td><code>uuid_ns_dns()</code></td>
<td>Constant designating the DNS namespace for UUIDs.</td>
</tr>
<tr>
<td><code>uuid_ns_url()</code></td>
<td>Constant designating the URL namespace for UUIDs.</td>
</tr>
<tr>
<td><code>uuid_ns_oid()</code></td>
<td>Constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in PostgreSQL.)</td>
</tr>
<tr>

</tr>
</tbody>
</table>
F.43.2. Building uuid-ossp

Historically this module depended on the OSSP UUID library, which accounts for the module’s name. While the OSSP UUID library can still be found at http://www.ossp.org/pkg/lib/uuid/, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. uuid-ossp can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core libc library. On Linux, OS X, and some other platforms, suitable functions are provided in the libuuid library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking configure, specify --with-uuid=bsd to use the BSD functions, or --with-uuid=e2fs to use e2fsprogs’ libuuid, or --with-uuid=ossp to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so configure does not automatically choose one.

Note: If you only need randomly-generated (version 4) UUIDs, consider using the gen_random_uuid() function from the pgcrypto module instead.

F.43.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.44. xml2

The xml2 module provides XPath querying and XSLT functionality.

F.44.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to <pgsql-hackers@lists.postgresql.org> so that the deficiency can be addressed.

F.44.2. Description of Functions

Table F-35 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries. All arguments are of type text, so for brevity that is not shown.

Table F-35. Functions
<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_is_well_formed(document)</td>
<td>bool</td>
<td>This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: before PostgreSQL 8.2, this function was called xml_valid(). That is the wrong name since validity and well-formedness have different meanings in XML. The old name is still available, but is deprecated.)</td>
</tr>
<tr>
<td>xpath_string(document, query)</td>
<td>text</td>
<td>These functions evaluate the XPath query on the supplied document, and cast the result to the specified type.</td>
</tr>
<tr>
<td>xpath_number(document, query)</td>
<td>float4</td>
<td></td>
</tr>
<tr>
<td>xpath_bool(document, query)</td>
<td>bool</td>
<td></td>
</tr>
<tr>
<td>xpath_nodeset(document, query, toptag, itemtag)</td>
<td>text</td>
<td>This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like: &lt;toptag&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;itemtag&gt;Value 1 which could be an XML fragment &lt;itemtag&gt;Value 2....&lt;/itemtag&gt; &lt;toptag&gt; If either toptag or itemtag is an empty string, the relevant tag is omitted.</td>
</tr>
<tr>
<td>xpath_nodeset(document, query)</td>
<td>text</td>
<td>Like xpath_nodeset(document, query, toptag, itemtag) but result omits both tags.</td>
</tr>
<tr>
<td>xpath_nodeset(document, query, itemtag)</td>
<td>text</td>
<td>Like xpath_nodeset(document, query, toptag, itemtag) but result omits toptag.</td>
</tr>
<tr>
<td>xpath_list(document, query, separator)</td>
<td>text</td>
<td>This function returns multiple values separated by the specified separator, for example Value 1,Value 2,Value 3 if separator is ,.</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath_list(document, query)</td>
<td>text</td>
<td>This is a wrapper for the above function that uses ``, as the separator.</td>
</tr>
</tbody>
</table>

F.44.3. xpath_table

xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record

xpath_table is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F-36.

Table F-36. xpath_table Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by `</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```sql
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be anything valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```sql
SELECT * FROM xpath_table('article_id',
    'article_xml',
    'articles',
    '/article/author|/article/pages|/article/title',
    ...
) AS table_name
```
Appendix F. Additional Supplied Modules

`AS t(article_id integer, author text, page_count integer, title text);`

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn’t necessarily have be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g. aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml,"/article/@date") > "2003-03-20" ')
    AS t(article_id integer, title text, author_id integer), tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.4.4.3.1. Multivalued Results

The xpath_table function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (id int PRIMARY KEY, xml text);

INSERT INTO test VALUES (1, '<doc num="C1">
  <line num="L1"><a>1</a><b>2</b><c>3</c></line>
  <line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">...
```
**Appendix F. Additional Supplied Modules**

```sql
SELECT * FROM xpath_table('id', 'xml', 'test', '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c', 'true')
AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

id | doc_num | line_num | val1 | val2 | val3
----+---------+----------+------+------+------
1 | C1      | L1       | 1    | 2    | 3
1 | L2      | 11       | 22   | 33   |
(2 rows)
```

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```sql
SELECT t.*, i.doc_num FROM xpath_table('id', 'xml', 'test', '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c', 'true')
AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
AS i(id int, doc_num varchar(10))
WHERE i.id = t.id AND i.id = 1
ORDER BY doc_num, line_num;

id | line_num | val1 | val2 | val3 | doc_num
----+----------+------+------+------+---------
1 | L1       | 1    | 2    | 3    | C1
1 | L2       | 11   | 22   | 33   | C1
(2 rows)
```

**F.44.4. XSLT Functions**

The following functions are available if libxslt is installed:

**F.44.4.1. xslt_process**

```
xslt_process(text document, text stylesheet, text paramlist) returns text
```

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!
There is also a two-parameter version of \texttt{xslt\_process} which does not pass any parameters to the transformation.

\section*{F.44.5. Author}

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as PostgreSQL.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. See Appendix F for more information about the contrib section in general and server extensions and plug-ins found in contrib specifically.

This appendix covers utility programs found in contrib. Once installed, either from source or a packaging system, they are found in the bin directory of the PostgreSQL installation and can be used like any other program.

G.1. Client Applications

This section covers PostgreSQL client applications in contrib. They can be run from anywhere, independent of where the database server resides. See also Reference II, PostgreSQL Client Applications for information about client applications that part of the core PostgreSQL distribution.

oid2name

Name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

Synopsis

oid2name [option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 63.

Note: The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables’ filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!
oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

**Options**

oid2name accepts the following command-line arguments:

- `-f filenode`
  
  show info for table with filenode *filenode*

- `-i`
  
  include indexes and sequences in the listing

- `-o oid`
  
  show info for table with OID *oid*

- `-q`
  
  omit headers (useful for scripting)

- `-s`
  
  show tablespace OIDs

- `-S`
  
  include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas)

- `-t tablename_pattern`
  
  show info for table(s) matching *tablename_pattern*

- `-V`
  
  --version
  
  Print the oid2name version and exit.

- `-x`
  
  display more information about each object shown: tablespace name, schema name, and OID

- `-?`
  
  --help
  
  Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

- `-d database`
  
  database to connect to

- `-H host`
  
  database server’s host
oid2name

-p port

database server’s port

-U username

user name to connect as

-P password

password (deprecated — putting this on the command line is a security hazard)

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it’s a LIKE pattern, so you can use things like foo%). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don’t give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.

If you don’t give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

$ # what’s in this database server, anyway?
$ oid2name

All databases:

<table>
<thead>
<tr>
<th>Oid</th>
<th>Database Name</th>
<th>Tablespace</th>
</tr>

Author

B. Palmer <bpalmer@crimelabs.net>
vacuumlo

Name
vacuumlo — remove orphaned large objects from a PostgreSQL database

Synopsis
vacuumlo [option...] dbname...

Description
vacuumlo is a simple utility program that will remove any “orphaned” large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any oid or lo data column of the database.

If you use this, you may also be interested in the lo_manage trigger in the lo module. lo_manage is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options
vacuumlo accepts the following command-line arguments:

-1 limit
  Remove no more than limit large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

-n
  Don’t remove anything, just show what would be done.

-v
  Write a lot of progress messages.

-V
  --version
  Print the vacuumlo version and exit.

-?  
  --help
  Show help about vacuumlo command line arguments, and exit.
vacuumlo accepts the following command-line arguments for connection parameters:

-h hostname
   Database server’s host.
-p port
   Database server’s port.
-U username
   User name to connect as.
-w
   --no-password
   Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.
-W
   Force vacuumlo to prompt for a password before connecting to a database.
   This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type oid or lo, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

G.2. Server Applications

This section covers PostgreSQL server-related applications in contrib. They are typically run on the host where the database server resides. See also Reference III, PostgreSQL Server Applications for information about server applications that part of the core PostgreSQL distribution.

pg_standby

Name

pg_standby — supports the creation of a PostgreSQL warm standby server

Synopsis

```
pg_standby [option...] archivelocation nextwalfile xlogfilepath [restartwalfile]
```

Description

pg_standby supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

pg_standby is designed to be a waiting restore_command, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see Section 25.2).

To configure a standby server to use pg_standby, put this into its recovery.conf configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where `archiveDir` is the directory from which WAL segment files should be restored.

If `restartwalfile` is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from `archivelocation`. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the `archivelocation` is a transient staging area for this particular standby server, but not when the `archivelocation` is intended as a long-term WAL archive area.

pg_standby assumes that `archivelocation` is a directory readable by the server-owning user. If `restartwalfile` (or `-k`) is specified, the `archivelocation` directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

**Smart Failover**

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.
Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word fast into it. pg_standby can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

Options

pg_standby accepts the following command-line arguments:

-\texttt{-c}

Use \texttt{cp} or \texttt{copy} command to restore WAL files from archive. This is the only supported behavior so this option is useless.

-\texttt{-d}

Print lots of debug logging output on \texttt{stderr}.

-\texttt{-k}

Remove files from \texttt{archivelocation} so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from \texttt{archivelocation}. This parameter will be silently ignored if \texttt{restartwalfile} is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is \texttt{deprecated} as of PostgreSQL 8.3; it is safer and more efficient to specify a \texttt{restartwalfile} parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

-\texttt{-r maxretries}

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for \texttt{sleeptime*num_retries} so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

-\texttt{-s sleeptime}

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult Section 25.2 for discussion.

-\texttt{-t triggerfile}

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example /tmp/pgsql.trigger.5432.

-\texttt{-V}

Print the \texttt{pg_standby} version and exit.
pg_standby

-w maxwaittime

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult Section 25.2 for discussion.

-?
--help

Show help about pg_standby command line arguments, and exit.

Notes

pg_standby is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the %r macro, which is designed to let pg_standby know the last file it needs to keep. With PostgreSQL 8.2, the -k option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the recovery_end_command option. Without this option a leftover trigger file can be hazardous.

pg_standby is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs.

Examples

On Linux or Unix systems, you might use:

archive_command = ‘cp %p .../archive/%f’

restore_command = ‘pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f %p %r 2>>standby.log’

recovery_end_command = ’rm -f /tmp/pgsql.trigger.5442’

where the archive directory is physically located on the standby server, so that the archive_command is accessing it across NFS, but the files are local to the standby (enabling use of ln). This will:

- produce debugging output in standby.log
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called /tmp/pgsql.trigger.5442 appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory
On Windows, you might use:

```plaintext
archive_command = 'copy %p ...\archive\%f'
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\archive %f %p %r 2>>standby.log'
recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits `sleeptime` seconds once it sees the proper file size. GNUWin32’s `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. Table H-1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin\(^1\), and there are several commercially available ones as well.

H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. Table H-2 lists some of these packages. Note that some of these projects might not be released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The contrib/ directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS\(^2\). Even PostgreSQL replication solutions can be developed externally. For example, Slony-I\(^3\) is a popular master/standby replication solution that is developed independently from the core project.

---

2. [http://postgis.net/](http://postgis.net/)
3. [http://www.slony.info](http://www.slony.info)
Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository. Our wiki, https://wiki.postgresql.org/wiki/Working_with_Git, has some discussion on working with Git. Note that building PostgreSQL from the source repository requires reasonably up-to-date versions of bison, flex, and Perl. These tools are not needed to build from a distribution tarball, because the files that these tools are used to build are included in the tarball. Other tool requirements are the same as shown in Section 15.2.

I.1. Getting The Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

Git

1. You will need an installed version of Git, which you can get from https://git-scm.com. Many systems already have a recent version of Git installed by default, or available in their package distribution system.

2. To begin using the Git repository, make a clone of the official mirror:
   
   ```
   git clone https://git.postgresql.org/git/postgresql.git
   ```

   This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory `postgresql` of your current directory.

   The Git mirror can also be reached via the Git protocol. Just change the URL prefix to `git`, as in:

   ```
   git clone git://git.postgresql.org/git/postgresql.git
   ```

3. Whenever you want to get the latest updates in the system, `cd` into the repository, and run:

   ```
   git fetch
   ```

   Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at https://git-scm.com.
Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF or PostScript, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF and PostScript format documentation is available separately for download.

J.1. DocBook

The documentation sources are written in DocBook, which is a markup language superficially similar to HTML. Both of these languages are applications of the Standard Generalized Markup Language, SGML, which is essentially a language for describing other languages. In what follows, the terms DocBook and SGML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group¹. The official DocBook site² has good introductory and reference documentation and a complete O’Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide³ is very helpful for beginners. The FreeBSD Documentation Project⁴ also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD⁵

This is the definition of DocBook itself. We currently use version 4.2; you cannot use later or earlier

¹. http://www.oasis-open.org
versions. You need the SGML variant of the DocBook DTD, but to build man pages you also need
the XML variant of the same version.

ISO 8879 character entities\(^6\)

These are required by DocBook but are distributed separately because they are maintained by ISO.

DocBook DSSSL Stylesheets\(^7\)

These contain the processing instructions for converting the DocBook sources to other formats, such
as HTML.

DocBook XSL Stylesheets\(^8\)

This is another stylesheet for converting DocBook to other formats. We currently use this to produce
man pages and optionally HTMLHelp. You can also use this toolchain to produce HTML or PDF
output, but official PostgreSQL releases use the DSSSL stylesheets for that.

The minimum required version is currently 1.74.0.

OpenJade\(^9\)

This is the base package of SGML processing. It contains an SGML parser, a DSSSL processor (that
is, a program to convert SGML to other formats using DSSSL stylesheets), as well as a number of
related tools. Jade is now being maintained by the OpenJade group, no longer by James Clark.

Libxml2\(^10\) for \texttt{xmlint}

This library and the \texttt{xmlint} tool it contains are used for processing XML. Many developers will
already have Libxml2 installed, because it is also used when building the PostgreSQL code. Note,
however, that \texttt{xmlint} might need to be installed from a separate subpackage.

Libxslt\(^11\) for \texttt{xsltproc}

This is the processing tool to use with the XSLT stylesheets (like \texttt{jade} is the processing tool for
DSSSL stylesheets).

JadeTeX\(^12\)

If you want to, you can also install JadeTeX to use TeX as a formatting backend for Jade. JadeTeX
can create PostScript or PDF files (the latter with bookmarks).

However, the output from JadeTeX is inferior to what you get from the RTF backend. Particular
problem areas are tables and various artifacts of vertical and horizontal spacing. Also, there is no
opportunity to manually polish the results.

We have documented experience with several installation methods for the various tools that are needed to
process the documentation. These will be described below. There might be some other packaged distribu-
tions for these tools. Please report package status to the documentation mailing list, and we will include
that information here.

\(^11\) http://xmlsoft.org/XSLT/
\(^12\) http://jadetex.sourceforge.net
J.2.1. Installation on Fedora, RHEL, and Derivatives

To install the required packages, use:

```
yum install docbook-dtds docbook-style-dsssl docbook-style-xsl libxslt openjade
```

J.2.2. Installation on FreeBSD

The FreeBSD Documentation Project is itself a heavy user of DocBook, so it comes as no surprise that there is a full set of “ports” of the documentation tools available on FreeBSD. The following ports need to be installed to build the documentation on FreeBSD.

- textproc/docbook-sgml
- textproc/docbook-xml
- textproc/docbook-xsl
- textproc/dsssl-docbook-modular
- textproc/libxslt
- textproc/openjade

A number of things from `/usr/ports/print (tex, jadetex)` might also be of interest.

More information about the FreeBSD documentation tools can be found in the FreeBSD Documentation Project’s instructions.\(^\text{13}\)

J.2.3. Debian Packages

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install docbook docbook-dsssl docbook-xsl libxml2-utils openjade1.3 opensp xsltproc
```

J.2.4. OS X

If you use MacPorts, the following will get you set up:

```
sudo port install docbook-dsssl docbook-sgml-4.2 docbook-xml-4.2 docbook-xsl libxslt openjade
```

J.2.5. Manual Installation from Source

The manual installation process of the DocBook tools is somewhat complex, so if you have pre-built packages available, use them. We describe here only a standard setup, with reasonably standard installation paths, and no “fancy” features. For details, you should study the documentation of the respective package, and read SGML introductory material.

J.2.5.1. Installing OpenJade

1. The installation of OpenJade offers a GNU-style `./configure; make; make install` build process. Details can be found in the OpenJade source distribution. In a nutshell:

   ```
   ./configure --enable-default-catalog=/usr/local/share/sgml/catalog
   make
   make install
   ```

   Be sure to remember where you put the “default catalog”; you will need it below. You can also leave it off, but then you will have to set the environment variable `SGML_CATALOG_FILES` to point to the file whenever you use jade later on. (This method is also an option if OpenJade is already installed and you want to install the rest of the toolchain locally.)

   **Note:** Some users have reported encountering a segmentation fault using OpenJade 1.4devel to build the PDFs, with a message like:

   ```
   openjade:.//stylesheet.dsl:664:2:E: flow object not accepted by port; only display flow objects accepted
   Downgrading to OpenJade 1.3 should get rid of this error.
   ```

2. Additionally, you should install the files `dsssl.dtd`, `fot.dtd`, `style-sheet.dtd`, and `catalog` from the `dsssl` directory somewhere, perhaps into `/usr/local/share/sgml/dsssl`. It’s probably easiest to copy the entire directory:

   ```
   cp -R dsssl /usr/local/share/sgml
   ```

3. Finally, create the file `/usr/local/share/sgml/catalog` and add this line to it:

   ```
   CATALOG "dsssl/catalog"
   ```

   (This is a relative path reference to the file installed in step 2. Be sure to adjust it if you chose your installation layout differently.)

J.2.5.2. Installing the DocBook DTD Kit

1. Obtain the DocBook V4.2 distribution\(^\text{14}\).

2. Create the directory `/usr/local/share/sgml/docbook-4.2` and change to it. (The exact location is irrelevant, but this one is reasonable within the layout we are following here.)

   ```
   mkdir /usr/local/share/sgml/docbook-4.2
   cd /usr/local/share/sgml/docbook-4.2
   ```

\(^\text{14}\) http://www.docbook.org/sgml/4.2/docbook-4.2.zip
3. Unpack the archive:

   `unzip -a ...../docbook-4.2.zip`
   (The archive will unpack its files into the current directory.)

4. Edit the file `/usr/local/share/sgml/catalog` (or whatever you told jade during installation) and put a line like this into it:

   `CATALOG "docbook-4.2/docbook.cat"`

5. Download the ISO 8879 character entities archive\(^{15}\), unpack it, and put the files in the same directory you put the DocBook files in:

   `cd /usr/local/share/sgml/docbook-4.2`
   `unzip ...../ISOEnts.zip`

6. Run the following command in the directory with the DocBook and ISO files:

   `perl -pi -e \'s/iso-(.*).gml/ISO\1/g\' docbook.cat`
   (This fixes a mixup between the names used in the DocBook catalog file and the actual names of the ISO character entity files.)

---

**J.2.5.3. Installing the DocBook DSSSL Style Sheets**

To install the style sheets, unzip and untar the distribution and move it to a suitable place, for example `/usr/local/share/sgml`. (The archive will automatically create a subdirectory.)

   `gunzip docbook-dsssl-1.xx.tar.gz`
   `tar -C /usr/local/share/sgml -xf docbook-dsssl-1.xx.tar`

The usual catalog entry in `/usr/local/share/sgml/catalog` can also be made:

   `CATALOG "docbook-dsssl-1.xx/catalog"`

Because stylesheets change rather often, and it's sometimes beneficial to try out alternative versions, PostgreSQL doesn't use this catalog entry. See Section J.2.6 for information about how to select the stylesheets instead.

---

**J.2.5.4. Installing JadeTeX**

To install and use JadeTeX, you will need a working installation of TeX and LaTeX2e, including the supported tools and graphics packages, Babel, AMS fonts and AMS-LaTeX, the PSNFSS extension and companion kit of “the 35 fonts”, the dvips program for generating PostScript, the macro packages fancy-hdr, hyperref, minitoc, url and ot2enc. All of these can be found on your friendly neighborhood CTAN site\(^{16}\). The installation of the TeX base system is far beyond the scope of this introduction. Binary packages should be available for any system that can run TeX.

Before you can use JadeTeX with the PostgreSQL documentation sources, you will need to increase the size of TeX's internal data structures. Details on this can be found in the JadeTeX installation instructions.

---

\(^{15}\) http://www.oasis-open.org/cover/ISOEnts.zip

\(^{16}\) http://www.ctan.org
Once that is finished you can install JadeTeX:

```
$ gunzip jadetex-xxx.tar.gz
$ tar xf jadetex-xxx.tar
$ cd jadetex
$ make install
$ mktexlsr
```

The last two need to be done as root.

**J.2.6. Detection by configure**

Before you can build the documentation you need to run the `configure` script as you would when building the PostgreSQL programs themselves. Check the output near the end of the run, it should look something like this:

```
checking for onsgmls... onsgmls
checking for openjade... openjade
checking for DocBook V4.2... yes
checking for DocBook stylesheets... /usr/share/sgml/docbook/stylesheet/dsssl/modular
checking for collateindex.pl... /usr/bin/collateindex.pl
checking for xsltproc... xsltproc
checking for osx... osx
```

If neither `onsgmls` nor `nsgmls` were found then some of the following tests will be skipped. `nsgmls` is part of the Jade package. You can pass the environment variables `JADE` and `NSGMLS` to `configure` to point to the programs if they are not found automatically. If “DocBook V4.2” was not found then you did not install the DocBook DTD kit in a place where Jade can find it, or you have not set up the catalog files correctly. See the installation hints above. The DocBook stylesheets are looked for in a number of relatively standard places, but if you have them some other place then you should set the environment variable `DOCBOOKSTYLE` to the location and rerun `configure` afterwards.

**J.3. Building The Documentation**

Once you have everything set up, change to the directory `doc/src/sgml` and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU make.)

**J.3.1. HTML**

To build the HTML version of the documentation:

```
doc/src/sgml$ make html
```

This is also the default target. The output appears in the subdirectory `html`.

2595
To create a proper index, the build might process several identical stages. If you do not care about the index, and just want to proof-read the output, use `draft`:

```
doc/src/sgml$ make draft
```

To build the documentation as a single HTML page, use:

```
doc/src/sgml$ make postgres.html
```

### J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook **refentry** pages to *roff output suitable for man pages. The man pages are also distributed as a tar archive, similar to the HTML version. To create the man pages, use the commands:

```
cd doc/src/sgml
make man
```

### J.3.3. Print Output via JadeTeX

If you want to use JadeTeX to produce a printable rendition of the documentation, you can use one of the following commands:

- To generate PostScript via DVI in A4 format:
  
  ```
doc/src/sgml$ make postgres-A4.ps
  ```
  In U.S. letter format:
  ```
doc/src/sgml$ make postgres-US.ps
  ```

- To make a PDF:
  ```
doc/src/sgml$ make postgres-A4.pdf
  ```
  or:
  ```
doc/src/sgml$ make postgres-US.pdf
  ```
  (Of course you can also make a PDF version from the PostScript, but if you generate PDF directly, it will have hyperlinks and other enhanced features.)

When using JadeTeX to build the PostgreSQL documentation, you will probably need to increase some of TeX’s internal parameters. These can be set in the file `texmf.cnf`. The following settings worked at the time of this writing:

```
hash_extra.jadetex = 200000
```
J.3.4. Overflow Text

Occasionally text is too wide for the printed margins, and in extreme cases, too wide for the printed page, e.g. non-wrapped text, wide tables. Overly wide text generates “Overfull hbox” messages in the TeX log output file, e.g. `postgres-US.log` or `postgres-A4.log`. There are 72 points in an inch so anything reported as over 72 points too wide will probably not fit on the printed page (assuming one inch margins). To find the SGML text causing the overflow, find the first page number mentioned above the overflow message, e.g. `[50 ###]` (page 50), and look at the page after that (e.g. page 51) in the PDF file to see the overflow text and adjust the SGML accordingly.

J.3.5. Print Output via RTF

You can also create a printable version of the PostgreSQL documentation by converting it to RTF and applying minor formatting corrections using an office suite. Depending on the capabilities of the particular office suite, you can then convert the documentation to PostScript or PDF. The procedure below illustrates this process using Applixware.

Note: It appears that current versions of the PostgreSQL documentation trigger some bug in or exceed the size limit of OpenJade. If the build process of the RTF version hangs for a long time and the output file still has size 0, then you might have hit that problem. (But keep in mind that a normal build takes 5 to 10 minutes, so don’t abort too soon.)

Applixware RTF Cleanup

OpenJade omits specifying a default style for body text. In the past, this undiagnosed problem led to a long process of table of contents generation. However, with great help from the Applixware folks the symptom was diagnosed and a workaround is available.

1. Generate the RTF version by typing:
   
   ```bash
doc/src/sgml$ make postgres.rtf
   ```

2. Repair the RTF file to correctly specify all styles, in particular the default style. If the document contains `refentry` sections, one must also replace formatting hints which tie a preceding paragraph
Appendix J. Documentation

to the current paragraph, and instead tie the current paragraph to the following one. A utility, fixrtf, is available in doc/src/sgml to accomplish these repairs:

```
doc/src/sgml$ ./fixrtf --refentry postgres.rtf
```

The script adds \{s0 Normal;\} as the zeroth style in the document. According to Applixware, the RTF standard would prohibit adding an implicit zeroth style, though Microsoft Word happens to handle this case. For repairing refentry sections, the script replaces \keepn tags with \keep.

3. Open a new document in Applixware Words and then import the RTF file.

4. Generate a new table of contents (ToC) using Applixware.

   a. Select the existing ToC lines, from the beginning of the first character on the first line to the last character of the last line.

   b. Build a new ToC using Tools → Book Building → Create Table of Contents. Select the first three levels of headers for inclusion in the ToC. This will replace the existing lines imported in the RTF with a native Applixware ToC.

   c. Adjust the ToC formatting by using Format → Style, selecting each of the three ToC styles, and adjusting the indents for First and Left. Use the following values:

<table>
<thead>
<tr>
<th>Style</th>
<th>First Indent (inches)</th>
<th>Left Indent (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOC-Heading 1</td>
<td>0.4</td>
<td>0.4</td>
</tr>
<tr>
<td>TOC-Heading 2</td>
<td>0.8</td>
<td>0.8</td>
</tr>
<tr>
<td>TOC-Heading 3</td>
<td>1.2</td>
<td>1.2</td>
</tr>
</tbody>
</table>

5. Work through the document to:

   • Adjust page breaks.
   • Adjust table column widths.

6. Replace the right-justified page numbers in the Examples and Figures portions of the ToC with correct values. This only takes a few minutes.

7. Delete the index section from the document if it is empty.

8. Regenerate and adjust the table of contents.

   a. Select the ToC field.

   b. Select Tools → Book Building → Create Table of Contents.

   c. Unbind the ToC by selecting Tools → Field Editing → Unprotect.

   d. Delete the first line in the ToC, which is an entry for the ToC itself.

9. Save the document as native Applixware Words format to allow easier last minute editing later.

10. “Print” the document to a file in PostScript format.
J.3.6. Plain Text Files

The installation instructions are also distributed as plain text, in case they are needed in a situation where better reading tools are not available. The INSTALL file corresponds to Chapter 15, with some minor changes to account for the different context. To recreate the file, change to the directory doc/src/sgml and enter make INSTALL.

In the past, the release notes and regression testing instructions were also distributed as plain text, but this practice has been discontinued.

J.3.7. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

doc/src/sgml$ make check

J.4. Documentation Authoring

SGML and DocBook do not suffer from an oversupply of open-source authoring tools. The most common tool set is the Emacs/XEmacs editor with appropriate editing mode. On some systems these tools are provided in a typical full installation.

J.4.1. Emacs/PSGML

PSGML is the most common and most powerful mode for editing SGML documents. When properly configured, it will allow you to use Emacs to insert tags and check markup consistency. You could use it for HTML as well. Check the PSGML web site\(^\text{17}\) for downloads, installation instructions, and detailed documentation.

There is one important thing to note with PSGML: its author assumed that your main SGML DTD directory would be /usr/local/lib/sgml. If, as in the examples in this chapter, you use /usr/local/share/sgml, you have to compensate for this, either by setting SGML\_CATALOG\_FILES environment variable, or you can customize your PSGML installation (its manual tells you how).

Put the following in your ~/.emacs environment file (adjusting the path names to be appropriate for your system):

```lisp
; ********** for SGML mode (psgml)
(setq sgml-omittag t)
(setq sgml-shorttag t)
(setq sgml-minimize-attributes nil)
(setq sgml-always-quote-attributes t)
```

\(^{17}\) http://www.lysator.liu.se/projects/about_psgml.html
Appendix J. Documentation

(setq sgml-indent-step 1)
(setq sgml-indent-data t)
(setq sgml-parent-document nil)
(setq sgml-exposed-tags nil)
(setq sgml-catalog-files '("/usr/local/share/sgml/catalog")

(autoload 'sgml-mode "psgml" "Major mode to edit SGML files." t )

and in the same file add an entry for SGML into the (existing) definition for auto-mode-alist:

(setq
  auto-mode-alist
    '(("\.sgml\$" . sgml-mode)

You might find that when using PSGML, a comfortable way of working with these separate files of book parts is to insert a proper DOCTYPE declaration while you’re editing them. If you are working on this source, for instance, it is an appendix chapter, so you would specify the document as an “appendix” instance of a DocBook document by making the first line look like this:

<!DOCTYPE appendix PUBLIC "-//OASIS//DTD DocBook V4.2//EN">

This means that anything and everything that reads SGML will get it right, and I can verify the document with nsgmls -s docguide.sgml. (But you need to take out that line before building the entire documentation set.)

J.4.2. Other Emacs Modes

GNU Emacs ships with a different SGML mode, which is not quite as powerful as PSGML, but it’s less confusing and lighter weight. Also, it offers syntax highlighting (font lock), which can be very helpful. src/tools/editors/emacs.samples contains sample settings for this mode.

Norm Walsh offers a major mode\footnote{http://nwalsh.com/emacs/docbookide/index.html} specifically for DocBook which also has font-lock and a number of features to reduce typing.

J.5. Style Guide

J.5.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

\footnote{http://nwalsh.com/emacs/docbookide/index.html}
Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

Name
This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

Synopsis
This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

Description
Several paragraphs explaining what the command does.

Options
A list describing each command-line option. If there are a lot of options, subsections can be used.

Exit Status
If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

Usage
Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

Environment
List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like `SHELL` might be of interest to the user.

Files
List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

Diagnostics
Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.

Notes
Anything that doesn’t fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

Examples
Examples
Appendix J. Documentation

History

If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.

Author

Author (only used in the contrib section)

See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.
Appendix K. Acronyms

This is a list of acronyms commonly used in the PostgreSQL documentation and in discussions about PostgreSQL.

ANSI
American National Standards Institute

API
Application Programming Interface

ASCII
American Standard Code for Information Interchange

BKI
Backend Interface

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site1.

SQL Reference Books

PostgreSQL-specific Documentation

Discusses SQL history and syntax, and describes the addition of INTERSECT and EXCEPT constructs into PostgreSQL. Prepared as a Master’s Thesis with the support of O. Univ. Prof. Dr. Georg Gottlob and Univ. Ass. Mag. Katrin Seyr at Vienna University of Technology.

Bibliography

Zelaine Fong. *The design and implementation of the POSTGRES query optimizer*, University of California, Berkeley, Computer Science Department.
