where `interval_start` is the start of the interval (Unix epoch format time stamp), `num_of_transactions` is the number of transactions within the interval, `latency_sum` is a sum of latencies (so you can compute average latency easily). The following two fields are useful for variance estimation - `latency_sum` is a sum of latencies and `latency_2_sum` is a sum of 2nd powers of latencies. The next two fields are `min_latency` - a minimum latency within the interval, and `max_latency` - maximum latency within the interval. A transaction is counted into the interval when it was committed. The fields in the end, `lag_sum`, `lag_2_sum`, `min_lag`, and `max_lag`, are only present if the `--rate` option is used. The very last one, `skipped_transactions`, is only present if the option `--latency-limit` is present, too. They are calculated from the time each transaction had to wait for the previous one to finish, i.e. the difference between each transaction’s scheduled start time and the time it actually started.

Here is example output:

```plaintext
1345828501 5601 1542744 483552416 61 2573
1345828503 7884 1979812 565806736 60 1479
```
Notice that while the plain (unaggregated) log file contains a reference to the custom script files, the aggregated log does not. Therefore if you need per script data, you need to aggregate the data on your own.

**Per-Statement Latencies**

With the `-r` option, pgbench collects the elapsed transaction time of each statement executed by every client. It then reports an average of those values, referred to as the latency for each statement, after the benchmark has finished.

For the default script, the output will look similar to this:

```
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 1
query mode: simple
number of clients: 10
number of threads: 1
number of transactions per client: 1000
number of transactions actually processed: 10000/10000
latency average = 15.844 ms
latency stddev = 2.715 ms
tps = 618.764555 (including connections establishing)
tps = 622.977698 (excluding connections establishing)
script statistics:
 - statement latencies in milliseconds:
   0.002 \set aid random(1, 100000 * :scale)
   0.005 \set bid random(1, 1 * :scale)
   0.002 \set tid random(1, 10 * :scale)
   0.001 \set delta random(-5000, 5000)
   0.326 BEGIN;
   0.603 UPDATE pgbench_accounts SET abalance = abalance + :delta WHERE aid = :aid;
   0.454 SELECT abalance FROM pgbench_accounts WHERE aid = :aid;
   5.528 UPDATE pgbench_tellers SET tbalance = tbalance + :delta WHERE tid = :tid;
   7.335 UPDATE pgbench_branches SET bbalance = bbalance + :delta WHERE bid = :bid;
   0.371 INSERT INTO pgbench_history (tid, bid, aid, delta, mtime) VALUES (:tid, :bid, :aid, :delta, CURRENT_TIMESTAMP);
   1.212 END;
```

If multiple script files are specified, the averages are reported separately for each script file.

Note that collecting the additional timing information needed for per-statement latency computation adds some overhead. This will slow average execution speed and lower the computed TPS. The amount of slowdown varies significantly depending on platform and hardware. Comparing average TPS values with and without latency reporting enabled is a good way to measure if the timing overhead is significant.
Good Practices

It is very easy to use pgbench to produce completely meaningless numbers. Here are some guidelines to help you get useful results.

In the first place, never believe any test that runs for only a few seconds. Use the -t or -T option to make the run last at least a few minutes, so as to average out noise. In some cases you could need hours to get numbers that are reproducible. It’s a good idea to try the test run a few times, to find out if your numbers are reproducible or not.

For the default TPC-B-like test scenario, the initialization scale factor (-s) should be at least as large as the largest number of clients you intend to test (-c); else you’ll mostly be measuring update contention. There are only -s rows in the pgbench_branches table, and every transaction wants to update one of them, so -c values in excess of -s will undoubtedly result in lots of transactions blocked waiting for other transactions.

The default test scenario is also quite sensitive to how long it’s been since the tables were initialized: accumulation of dead rows and dead space in the tables changes the results. To understand the results you must keep track of the total number of updates and when vacuuming happens. If autovacuum is enabled it can result in unpredictable changes in measured performance.

A limitation of pgbench is that it can itself become the bottleneck when trying to test a large number of client sessions. This can be alleviated by running pgbench on a different machine from the database server, although low network latency will be essential. It might even be useful to run several pgbench instances concurrently, on several client machines, against the same database server.

Security

If untrusted users have access to a database that has not adopted a secure schema usage pattern, do not run pgbench in that database. pgbench uses unqualified names and does not manipulate the search path.
pg_config

Name

pg_config — retrieve information about the installed version of PostgreSQL.

Synopsis

pg_config [option...]

Description

The pg_config utility prints configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries.

Options

To use pg_config, supply one or more of the following options:

--bindir
Print the location of user executables. Use this, for example, to find the psql program. This is normally also the location where the pg_config program resides.

--docdir
Print the location of documentation files.

--htmldir
Print the location of HTML documentation files.

--includedir
Print the location of C header files of the client interfaces.

--pkgincludedir
Print the location of other C header files.

--includedir-server
Print the location of C header files for server programming.

--libdir
Print the location of object code libraries.

--pkglibdir
Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files might also be installed in this directory.)

--localedir
Print the location of locale support files. (This will be an empty string if locale support was not configured when PostgreSQL was built.)
--mandir
Print the location of manual pages.

--sharedir
Print the location of architecture-independent support files.

--sysconfdir
Print the location of system-wide configuration files.

--pgxs
Print the location of extension makefiles.

--configure
Print the options that were given to the configure script when PostgreSQL was configured for building. This can be used to reproduce the identical configuration, or to find out with what options a binary package was built. (Note however that binary packages often contain vendor-specific custom patches.) See also the examples below.

--cc
Print the value of the cc variable that was used for building PostgreSQL. This shows the C compiler used.

--cppflags
Print the value of the CPPFLAGS variable that was used for building PostgreSQL. This shows C compiler switches needed at preprocessing time (typically, -I switches).

--cflags
Print the value of the CFLAGS variable that was used for building PostgreSQL. This shows C compiler switches.

--cflags_sl
Print the value of the CFLAGS_SL variable that was used for building PostgreSQL. This shows extra C compiler switches used for building shared libraries.

--ldflags
Print the value of the LDFLAGS variable that was used for building PostgreSQL. This shows linker switches.

--ldflags_ex
Print the value of the LDFLAGS_EX variable that was used for building PostgreSQL. This shows linker switches used for building executables only.

--ldflags_sl
Print the value of the LDFLAGS_SL variable that was used for building PostgreSQL. This shows linker switches used for building shared libraries only.

--libs
Print the value of the LIBS variable that was used for building PostgreSQL. This normally contains -l switches for external libraries linked into PostgreSQL.

--version
Print the version of PostgreSQL.
pg_config

-?
--help

    Show help about pg_config command line arguments, and exit.

If more than one option is given, the information is printed in that order, one item per line. If no
options are given, all available information is printed, with labels.

Notes

The options --docdir, --pkgincludedir, --localedir, --mandir, --sharedir,
--sysconfdir, --cc, --cppflags, --cflags, --cflags_sl, --ldflags, --ldflags_sl,
and --libs were added in PostgreSQL 8.1. The option --htmldir was added in PostgreSQL 8.4.
The option --ldflags_ex was added in PostgreSQL 9.0.

Example

To reproduce the build configuration of the current PostgreSQL installation, run the following com-
mand:

eval ./configure 'pg_config --configure'

The output of pg_config --configure contains shell quotation marks so arguments with spaces
are represented correctly. Therefore, using eval is required for proper results.
pg_dump

Name

pg_dump — extract a PostgreSQL database into a script file or other archive file

Synopsis

pg_dump [connection-option...] [option...] [dbname]

Description

pg_dump is a utility for backing up a PostgreSQL database. It makes consistent backups even if the database is being used concurrently. pg_dump does not block other users accessing the database (readers or writers).

pg_dump only dumps a single database. To backup global objects that are common to all databases in a cluster, such as roles and tablespaces, use pg_dumpall.

Dumps can be output in script or archive file formats. Script dumps are plain-text files containing the SQL commands required to reconstruct the database to the state it was in at the time it was saved. To restore from such a script, feed it to psql. Script files can be used to reconstruct the database even on other machines and other architectures; with some modifications, even on other SQL database products.

The alternative archive file formats must be used with pg_restore to rebuild the database. They allow pg_restore to be selective about what is restored, or even to reorder the items prior to being restored. The archive file formats are designed to be portable across architectures.

When used with one of the archive file formats and combined with pg_restore, pg_dump provides a flexible archival and transfer mechanism. pg_dump can be used to backup an entire database, then pg_restore can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the “custom” format (-Fc) and the “directory” format (-Fd). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The “directory” format is the only format that supports parallel dumps.

While running pg_dump, one should examine the output for any warnings (printed on standard error), especially in light of the limitations listed below.

Options

The following command-line options control the content and format of the output.

dbname

  Specifies the name of the database to be dumped. If this is not specified, the environment variable PGDATABASE is used. If that is not set, the user name specified for the connection is used.
Dump only the data, not the schema (data definitions). Table data, large objects, and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying \[--section=data\].

Include large objects in the dump. This is the default behavior except when \[--schema,--table,\]

or \[--schema-only\] is specified. The \[-b\] switch is therefore only useful to add large objects to

dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when \[--data-only\] is used, but not when \[--schema-only\] is.

Output commands to clean (drop) database objects prior to outputting the commands for creating them. (Unless \[--if-exists\] is also specified, restore might generate some harmless error messages, if any objects were not present in the destination database.)

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call \[pg_restore\].

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn’t matter which database in the destination installation you connect to before running the script.) If \[--clean\] is also specified, the script drops and recreates the target database before reconnecting to it.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call \[pg_restore\].

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the \[PGCLIENTENCODING\] environment variable to the desired dump encoding.)

Send output to the specified file. This parameter can be omitted for file based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by \[pg_dump\] and must not exist before.

Selects the format of the output. \[format\] can be one of the following:

\[p\]

Output a plain-text SQL script file (the default).
pg_dump

c

Custom

Output a custom-format archive suitable for input into pg_restore. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is also compressed by default.

d

Directory

Output a directory-format archive suitable for input into pg_restore. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that pg_restore can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the gzip tool. This format is compressed by default and also supports parallel dumps.

T

Tar

Output a tar-format archive suitable for input into pg_restore. The tar format is compatible with the directory format: extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.

-\(j\) \textit{njobs}

--jobs=\textit{njobs}

Run the dump in parallel by dumping \textit{njobs} tables simultaneously. This option reduces the time of the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

\texttt{pg\_dump} will open \textit{njobs} + 1 connections to the database, so make sure your \texttt{max\_connections} setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the \texttt{pg\_dump} master process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the master process to be released. Consequently any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the \texttt{pg\_dump} worker process requests another shared lock using the \texttt{NOWAIT} option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so \texttt{pg\_dump} has no choice but to abort the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in PostgreSQL 9.2. With this feature, database clients can ensure they see the same data set even though they use different connections. \texttt{pg\_dump} \(-j\) uses multiple database connections; it connects to the database once with the master process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn’t be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.
If you want to run a parallel dump of a pre-9.2 server, you need to make sure that the database content doesn’t change from between the time the master connects to the database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the --no-synchronized-snapshots parameter when running pg_dump -j against a pre-9.2 PostgreSQL server.

-n schema
--schema=schema

Dump only schemas matching schema; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple -n switches. Also, the schema parameter is interpreted as a pattern according to the same rules used by psql’s \d commands (see Patterns), so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples.

Note: When -n is specified, pg_dump makes no attempt to dump any other database objects that the selected schema(s) might depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

Note: Non-schema objects such as blobs are not dumped when -n is specified. You can add blobs back to the dump with the --blobs switch.

-N schema
--exclude-schema=schema

Do not dump any schemas matching the schema pattern. The pattern is interpreted according to the same rules as for -n. -N can be given more than once to exclude schemas matching any of several patterns.

When both -n and -N are given, the behavior is to dump just the schemas that match at least one -n switch but no -N switches. If -N appears without -n, then schemas matching -N are excluded from what is otherwise a normal dump.

-o
--oids

Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

-O
--no-owner

Do not output commands to set ownership of objects to match the original database. By default, pg_dump issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify -O.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call pg_restore.
pg_dump

-\(R\)
--no-reconnect

This option is obsolete but still accepted for backwards compatibility.

-s
--schema-only

Dump only the object definitions (schema), not data.

This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying --section=pre-data --section=post-data.

(Do not confuse this with the --schema option, which uses the word “schema” in a different meaning.)

To exclude table data for only a subset of tables in the database, see --exclude-table-data.

-S username
--superuser=username

Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used. (Usually, it’s better to leave this out, and instead start the resulting script as superuser.)

-t table
--table=table

Dump only tables with names matching table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple \(t\) switches. Also, the table parameter is interpreted as a pattern according to the same rules used by psql’s \(d\) commands (see Patterns), so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards; see Examples.

The -n and -N switches have no effect when -t is used, because tables selected by -t will be dumped regardless of those switches, and non-table objects will not be dumped.

Note: When -t is specified, pg_dump makes no attempt to dump any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

Note: The behavior of the -t switch is not entirely upward compatible with pre-8.2 PostgreSQL versions. Formerly, writing -t tab would dump all tables named tab, but now it just dumps whichever one is visible in your default search path. To get the old behavior you can write -t ‘+.tab’. Also, you must write something like -t sch.tab to select a table in a particular schema, rather than the old locution of -n sch -t tab.

-T table
--exclude-table=table

Do not dump any tables matching the table pattern. The pattern is interpreted according to the same rules as for -t. -T can be given more than once to exclude tables matching any of several patterns.
When both \( -t \) and \( -T \) are given, the behavior is to dump just the tables that match at least one \( -t \) switch but no \( -T \) switches. If \( -T \) appears without \( -t \), then tables matching \( -T \) are excluded from what is otherwise a normal dump.

\( -v \)
--verbose

Specifies verbose mode. This will cause pg_dump to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

\( -V \)
--version

Print the pg_dump version and exit.

\( -x \)
--no-privileges
--no-acl

Prevent dumping of access privileges (grant/revoke commands).

\( -Z \) 0..9
--compress=0..9

Specify the compression level to use. Zero means no compression. For the custom archive format, this specifies compression of individual table-data segments, and the default is to compress at a moderate level. For plain text output, setting a nonzero compression level causes the entire output file to be compressed, as though it had been fed through gzip; but the default is not to compress. The tar archive format currently does not support compression at all.

--binary-upgrade

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts
--attribute-inserts

Dump data as INSERT commands with explicit column names (INSERT INTO table (column, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

--disable-dollar-quoting

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers

This option is relevant only when creating a data-only dump. It instructs pg_dump to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with \( -s \), or preferably be careful to start the resulting script as a superuser.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call pg_restore.
--enable-row-security

This option is relevant only when dumping the contents of a table which has row security. By default, pg_dump will set row_security to off, to ensure that all data is dumped from the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs pg_dump to set row_security to on instead, allowing the user to dump the parts of the contents of the table that they have access to.

Note that if you use this option currently, you probably also want the dump be in INSERT format, as the COPY FROM during restore does not support row security.

--exclude-table-data=table

Do not dump data for any tables matching the table pattern. The pattern is interpreted according to the same rules as for -t. --exclude-table-data can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see --schema-only.

--if-exists

Use conditional commands (i.e. add an IF EXISTS clause) when cleaning database objects. This option is not valid unless --clean is also specified.

--inserts

Dump data as INSERT commands (rather than COPY). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore might fail altogether if you have rearranged column order. The --column-inserts option is safe against column order changes, though even slower.

--lock-wait-timeout=timeout

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by SET statement_timeout. (Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions since 7.3. This option is ignored when dumping from a pre-7.3 server.)

--no-security-labels

Do not dump security labels.

--no-synchronized-snapshots

This option allows running pg_dump -j against a pre-9.2 server, see the documentation of the -j parameter for more details.

--no-tablespaces

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call pg_restore.

--no-unlogged-table-data

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.
--quote-all-identifiers

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose PostgreSQL major version is different from pg_dump’s, or when the output is intended to be loaded into a server of a different major version. By default, pg_dump quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using --quote-all-identifiers prevents such issues, at the price of a harder-to-read dump script.

--section=sectionname

Only dump the named section. The section name can be pre-data, data, or post-data. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The data section contains actual table data, large-object contents, and sequence values. Post-data items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. Pre-data items include all other data definition items.

--serializable-deferrable

Use a serializable transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn’t a risk of the dump failing or causing other transactions to roll back with a serialization_failure. See Chapter 13 for more information about transaction isolation and concurrency control.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when pg_dump is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

--snapshot=snapshotname

Use the specified synchronized snapshot when making a dump of the database (see Table 9-81 for more details).

This option is useful when needing to synchronize the dump with a logical replication slot (see Chapter 47) or with a concurrent session.

In the case of a parallel dump, the snapshot name defined by this option is used rather than taking a new snapshot.

--strict-names

Require that each schema (-n|--schema) and table (-t|--table) qualifier match at least one schema/table in the database to be dumped. Note that if none of the schema/table qualifiers find matches, pg_dump will generate an error even without --strict-names.

This option has no effect on -N|--exclude-schema, -T|--exclude-table, or --exclude-table-data. An exclude pattern failing to match any objects is not considered an error.
pg_dump

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly. Also, a dump using SET SESSION AUTHORIZATION will certainly require superuser privileges to restore correctly, whereas ALTER OWNER requires lesser privileges.

-?
--help

Show help about pg_dump command line arguments, and exit.

The following command-line options control the database connection parameters.

-d dbname
--dbname=
dbname

Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

If this parameter contains an = sign or starts with a valid URI prefix (postgresql:// or postgres://), it is treated as a conninfo string. See Section 32.1 for more information.

-h host
--host=
host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=
port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=
username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_dump to prompt for a password before connecting to a database.

This option is never essential, since pg_dump will automatically prompt for a password if the server demands password authentication. However, pg_dump will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.
--role=rolename

Specifies a role name to be used to create the dump. This option causes pg_dump to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_dump, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGDATABASE
PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

Diagnostics

pg_dump internally executes SELECT statements. If you have problems running pg_dump, make sure you are able to select information from the database using, for example, psql. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

The database activity of pg_dump is normally collected by the statistics collector. If this is undesirable, you can set parameter track_counts to false via PGOPTIONS or the ALTER USER command.

Notes

If your database cluster has any local additions to the template1 database, be careful to restore the output of pg_dump into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from template0 not template1, for example:

CREATE DATABASE foo WITH TEMPLATE template0;

When a data-only dump is chosen and the option --disable-triggers is used, pg_dump emits commands to disable triggers on user tables before inserting the data, and then commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

The dump file produced by pg_dump does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run ANALYZE after restoring from a dump file to ensure optimal performance; see Section 24.1.3 and Section 24.1.6 for more information. The dump file also does not contain any ALTER DATABASE ... SET commands; these settings are dumped by pg_dumpall, along with database users and other installation-wide settings.
Because pg_dump is used to transfer data to newer versions of PostgreSQL, the output of pg_dump can be expected to load into PostgreSQL server versions newer than pg_dump’s version. pg_dump can also dump from PostgreSQL servers older than its own version. (Currently, servers back to version 7.0 are supported.) However, pg_dump cannot dump from PostgreSQL servers newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that pg_dump’s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the --quote-all-identifiers option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different PostgreSQL versions.

Examples

To dump a database called mydb into a SQL-script file:

```bash
$ pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named newdb:

```bash
$ psql -d newdb -f db.sql
```

To dump a database into a custom-format archive file:

```bash
$ pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```bash
$ pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```bash
$ pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named newdb:

```bash
$ pg_restore -d newdb db.dump
```

To dump a single table named mytab:

```bash
$ pg_dump -t mytab mydb > db.sql
```

To dump all tables whose names start with emp in the detroit schema, except for the table named employee_log:

```bash
$ pg_dump -t 'detroit.emp*' -T detroit.employee_log mydb > db.sql
```
To dump all schemas whose names start with east or west and end in gsm, excluding any schemas whose names contain the word test:

```
$ pg_dump -n 'east*gsm' -n 'west*gsm' -N '*test*' mydb > db.sql
```

The same, using regular expression notation to consolidate the switches:

```
$ pg_dump -n '(east|west)*gsm' -N '*test*' mydb > db.sql
```

To dump all database objects except for tables whose names begin with ts_:

```
$ pg_dump -T 'ts_*' mydb > db.sql
```

To specify an upper-case or mixed-case name in -t and related switches, you need to double-quote the name; else it will be folded to lower case (see Patterns). But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like

```
$ pg_dump -t "\"MixedCaseName\"" mydb > mytab.sql
```

pg_dumpall, pg_restore, psql
**pg_dumpall**

**Name**

pg_dumpall — extract a PostgreSQL database cluster into a script file

**Synopsis**

pg_dumpall [connection-option...][option...]

**Description**

pg_dumpall is a utility for writing out ("dumping") all PostgreSQL databases of a cluster into one script file. The script file contains SQL commands that can be used as input to psql to restore the databases. It does this by calling pg_dump for each database in a cluster. pg_dumpall also dumps global objects that are common to all databases. (pg_dump does not save these objects.) This currently includes information about database users and groups, tablespaces, and properties such as access permissions that apply to databases as a whole.

Since pg_dumpall reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to execute the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Use the [-f file] option or shell operators to redirect it into a file.

pg_dumpall needs to connect several times to the PostgreSQL server (once per database). If you use password authentication it will ask for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 32.15 for more information.

**Options**

The following command-line options control the content and format of the output.

- `-a`
  **--data-only**
  Dump only the data, not the schema (data definitions).

- `-c`
  **--clean**
  Include SQL commands to clean (drop) databases before recreating them. DROP commands for roles and tablespaces are added as well.

- `-f filename`
  **--file=filename**
  Send output to the specified file. If this is omitted, the standard output is used.
pg_dumpall

-\-g
--globals-only
Dump only global objects (roles and tablespaces), no databases.

-\-o
--oids
Dump object identifiers (OIDs) as part of the data for every table. Use this option if your application references the OID columns in some way (e.g., in a foreign key constraint). Otherwise, this option should not be used.

-\-O
--no-owner
Do not output commands to set ownership of objects to match the original database. By default, pg_dumpall issues ALTER OWNER or SET SESSION AUTHORIZATION statements to set ownership of created schema elements. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify -\-O.

-\-r
--roles-only
Dump only roles, no databases or tablespaces.

-\-s
--schema-only
Dump only the object definitions (schema), not data.

-\-S username
--superuser=username
Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used. (Usually, it’s better to leave this out, and instead start the resulting script as superuser.)

-\-t
--tablespaces-only
Dump only tablespaces, no databases or roles.

-\-v
--verbose
Specifies verbose mode. This will cause pg_dumpall to output start/stop times to the dump file, and progress messages to standard error. It will also enable verbose output in pg_dump.

-\-V
--version
Print the pg_dumpall version and exit.

-\-x
--no-privileges
--no-acl
Prevent dumping of access privileges (grant/revoke commands).
--binary-upgrade

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

--column-inserts
--attribute-inserts

Dump data as INSERT commands with explicit column names (INSERT INTO table (column, ...) VALUES ...). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases.

--disable-dollar-quoting

This option disables the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

--disable-triggers

This option is relevant only when creating a data-only dump. It instructs pg_dumpall to include commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So, you should also specify a superuser name with -S, or preferably be careful to start the resulting script as a superuser.

--if-exists

Use conditional commands (i.e. add an IF EXISTS clause) to clean databases and other objects. This option is not valid unless --clean is also specified.

--inserts

Dump data as INSERT commands (rather than COPY). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL databases. Note that the restore might fail altogether if you have rearranged column order. The --column-inserts option is safer, though even slower.

--lock-wait-timeout=timeout

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by SET statement_timeout. Allowed values vary depending on the server version you are dumping from, but an integer number of milliseconds is accepted by all versions since 7.3. This option is ignored when dumping from a pre-7.3 server.

--no-security-labels

Do not dump security labels.

--no-tablespaces

Do not output commands to create tablespaces nor select tablespaces for objects. With this option, all objects will be created in whichever tablespace is the default during restore.

--no-unlogged-table-data

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.
pg_dumpall

--quote-all-identifiers

Force quoting of all identifiers. This option is recommended when dumping a database from a
server whose PostgreSQL major version is different from pg_dumpall’s, or when the output is
intended to be loaded into a server of a different major version. By default, pg_dumpall quotes
only identifiers that are reserved words in its own major version. This sometimes results in com-
patibility issues when dealing with servers of other versions that may have slightly different sets
of reserved words. Using --quote-all-identifiers prevents such issues, at the price of a
harder-to-read dump script.

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER
commands to determine object ownership. This makes the dump more standards compatible,
but depending on the history of the objects in the dump, might not restore properly.

-?  --help

Show help about pg_dumpall command line arguments, and exit.

The following command-line options control the database connection parameters.

-d connstr
--dbname=connstr

Specifies parameters used to connect to the server, as a connection string. See Section 32.1.1 for
more information.

The option is called --dbname for consistency with other client applications, but because
pg_dumpall needs to connect to many databases, database name in the connection string will be
ignored. Use -l option to specify the name of the database used to dump global objects and to
discover what other databases should be dumped.

-h host
--host=host

Specifies the host name of the machine on which the database server is running. If the value
begins with a slash, it is used as the directory for the Unix domain socket. The default is taken
from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-l dbname
--database=dbname

Specifies the name of the database to connect to for dumping global objects and discovering
what other databases should be dumped. If not specified, the postgres database will be used,
and if that does not exist, template1 will be used.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening
for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=username

User name to connect as.
Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-\w
--no-password

Force pg_dumpall to prompt for a password before connecting to a database.

This option is never essential, since pg_dumpall will automatically prompt for a password if the server demands password authentication. However, pg_dumpall will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -w to avoid the extra connection attempt.

Note that the password prompt will occur again for each database to be dumped. Usually, it’s better to set up a ~/.pgpass file than to rely on manual password entry.

--role=rolename

Specifies a role name to be used to create the dump. This option causes pg_dumpall to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -u) lacks privileges needed by pg_dumpall, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

Environment

PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

Notes

Since pg_dumpall calls pg_dump internally, some diagnostic messages will refer to pg_dump.

Once restored, it is wise to run ANALYZE on each database so the optimizer has useful statistics. You can also run vacuumdb -a -z to analyze all databases.

pg_dumpall requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.
Examples

To dump all databases:

```bash
$ pg_dumpall > db.out
```

To reload database(s) from this file, you can use:

```bash
$ psql -f db.out postgres
```

(It is not important to which database you connect here since the script file created by pg_dumpall will contain the appropriate commands to create and connect to the saved databases.)

See Also

Check pg_dump for details on possible error conditions.
pg_isready

Name

pg_isready — check the connection status of a PostgreSQL server

Synopsis

pg_isready [connection-option...] [option...]

Description

pg_isready is a utility for checking the connection status of a PostgreSQL database server. The exit status specifies the result of the connection check.

Options

- **d dbname**
  --dbname=dbname

  Specifies the name of the database to connect to.

  If this parameter contains an = sign or starts with a valid URI prefix (postgresql:// or postgres://), it is treated as a conninfo string. See Section 32.1.1 for more information.

- **h hostname**
  --host=hostname

  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix-domain socket.

- **p port**
  --port=port

  Specifies the TCP port or the local Unix-domain socket file extension on which the server is listening for connections. Defaults to the value of the PGPORT environment variable or, if not set, to the port specified at compile time, usually 5432.

- **q**
  --quiet

  Do not display status message. This is useful when scripting.

- **t seconds**
  --timeout=seconds

  The maximum number of seconds to wait when attempting connection before returning that the server is not responding. Setting to 0 disables. The default is 3 seconds.

- **U username**
  --username=username

  Connect to the database as the user username instead of the default.
-V
--version

Print the pg_isready version and exit.

-?
--help

Show help about pg_isready command line arguments, and exit.

Exit Status
pg_isready returns 0 to the shell if the server is accepting connections normally, 1 if the server is rejecting connections (for example during startup), 2 if there was no response to the connection attempt, and 3 if no attempt was made (for example due to invalid parameters).

Environment
pg_isready, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

Notes
It is not necessary to supply correct user name, password, or database name values to obtain the server status; however, if incorrect values are provided, the server will log a failed connection attempt.

Examples
Standard Usage:

$ pg_isready
/tmp:5432 - accepting connections
$ echo $? 0

Running with connection parameters to a PostgreSQL cluster in startup:

$ pg_isready -h localhost -p 5433
localhost:5433 - rejecting connections
$ echo $? 1

Running with connection parameters to a non-responsive PostgreSQL cluster:

$ pg_isready -h someremotehost
someremotehost:5432 - no response
$ echo $? 2
\textit{pg\_isready}
**pg_receivexlog**

**Name**

`pg_receivexlog` — stream transaction logs from a PostgreSQL server

**Synopsis**

```
pg_receivexlog [option...]
```

**Description**

`pg_receivexlog` is used to stream the transaction log from a running PostgreSQL cluster. The transaction log is streamed using the streaming replication protocol, and is written to a local directory of files. This directory can be used as the archive location for doing a restore using point-in-time recovery (see Section 25.3).

`pg_receivexlog` streams the transaction log in real time as it’s being generated on the server, and does not wait for segments to complete like `archive_command` does. For this reason, it is not necessary to set `archive_timeout` when using `pg_receivexlog`.

Unlike the WAL receiver of a PostgreSQL standby server, `pg_receivexlog` by default flushes WAL data only when a WAL file is closed. The option `--synchronous` must be specified to flush WAL data in real time.

The transaction log is streamed over a regular PostgreSQL connection and uses the replication protocol. The connection must be made with a superuser or a user having `REPLICATION` permissions (see Section 21.2), and `pg_hba.conf` must permit the replication connection. The server must also be configured with `max_wal_senders` set high enough to leave at least one session available for the stream.

If the connection is lost, or if it cannot be initially established, with a non-fatal error, `pg_receivexlog` will retry the connection indefinitely, and reestablish streaming as soon as possible. To avoid this behavior, use the `-n` parameter.

**Options**

```
-D directory
--directory=directory

   Directory to write the output to.
   This parameter is required.
--if-not-exists

   Do not error out when `--create-slot` is specified and a slot with the specified name already exists.
-n
--no-loop

   Don’t loop on connection errors. Instead, exit right away with an error.
```
-s interval
--status-interval=interval

Specifies the number of seconds between status packets sent back to the server. This allows for
easier monitoring of the progress from server. A value of zero disables the periodic status updates
completely, although an update will still be sent when requested by the server, to avoid timeout
disconnect. The default value is 10 seconds.

-S slotname
--slot=slotname

Require pg_receivexlog to use an existing replication slot (see Section 26.2.6). When this option
is used, pg_receivexlog will report a flush position to the server, indicating when each segment
has been synchronized to disk so that the server can remove that segment if it is not otherwise
needed.

When the replication client of pg_receivexlog is configured on the server as a synchronous
standby, then using a replication slot will report the flush position to the server, but only when a
WAL file is closed. Therefore, that configuration will cause transactions on the primary to wait
for a long time and effectively not work satisfactorily. The option --synchronous (see below)
must be specified in addition to make this work correctly.

--synchronous

Flush the WAL data to disk immediately after it has been received. Also send a status packet
back to the server immediately after flushing, regardless of --status-interval.

This option should be specified if the replication client of pg_receivexlog is configured on the
server as a synchronous standby, to ensure that timely feedback is sent to the server.

-v
--verbose

Enables verbose mode.

The following command-line options control the database connection parameters.

-d connstr
--dbname=connstr

Specifies parameters used to connect to the server, as a connection string. See Section 32.1.1 for
more information.

The option is called --dbname for consistency with other client applications, but because
pg_receivexlog doesn’t connect to any particular database in the cluster, database name in the
connection string will be ignored.

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with
a slash, it is used as the directory for the Unix domain socket. The default is taken from the
PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening
for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.
pg_receivexlog

- U username
- --username=username

User name to connect as.

-w
- --no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
- --password

Force pg_receivexlog to prompt for a password before connecting to a database. This option is never essential, since pg_receivexlog will automatically prompt for a password if the server demands password authentication. However, pg_receivexlog will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

pg_receivexlog can perform one of the two following actions in order to control physical replication slots:

- --create-slot

Create a new physical replication slot with the name specified in --slot, then exit.

- --drop-slot

Drop the replication slot with the name specified in --slot, then exit.

Other options are also available:

- V
- --version

Print the pg_receivexlog version and exit.

-?
- --help

Show help about pg_receivexlog command line arguments, and exit.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 32.14).

Notes

When using pg_receivexlog instead of archive_command as the main WAL backup method, it is strongly recommended to use replication slots. Otherwise, the server is free to recycle or remove transaction log files before they are backed up, because it does not have any information, either from
archive_command or the replication slots, about how far the WAL stream has been archived. Note, however, that a replication slot will fill up the server’s disk space if the receiver does not keep up with fetching the WAL data.

Examples

To stream the transaction log from the server at mydbserver and store it in the local directory /usr/local/pgsql/archive:

```
$ pg_receivexlog -h mydbserver -D /usr/local/pgsql/archive
```

See Also

pg_basebackup
**Name**

`pg_recvlogical` — control PostgreSQL logical decoding streams

**Synopsis**

`pg_recvlogical` [option...]

**Description**

`pg_recvlogical` controls logical decoding replication slots and streams data from such replication slots. It creates a replication-mode connection, so it is subject to the same constraints as `pg_recvexlog`, plus those for logical replication (see Chapter 47).

**Options**

At least one of the following options must be specified to select an action:

- `--create-slot`
  
  Create a new logical replication slot with the name specified by `--slot`, using the output plugin specified by `--plugin`, for the database specified by `--dbname`.

- `--drop-slot`
  
  Drop the replication slot with the name specified by `--slot`, then exit.

- `--start`
  
  Begin streaming changes from the logical replication slot specified by `--slot`, continuing until terminated by a signal. If the server side change stream ends with a server shutdown or disconnect, retry in a loop unless `--no-loop` is specified.
  
  The stream format is determined by the output plugin specified when the slot was created.
  
  The connection must be to the same database used to create the slot.

`--create-slot` and `--start` can be specified together. `--drop-slot` cannot be combined with another action.

The following command-line options control the location and format of the output and other replication behavior:

- `-f filename`
  
  Write received and decoded transaction data into this file. Use `-` for stdout.
-F interval_seconds
--fsync-interval=interval_seconds

Specifies how often pg_recvlogical should issue fsync() calls to ensure the output file is safely flushed to disk.

The server will occasionally request the client to perform a flush and report the flush position to the server. This setting is in addition to that, to perform flushes more frequently.

Specifying an interval of 0 disables issuing fsync() calls altogether, while still reporting progress to the server. In this case, data could be lost in the event of a crash.

-I lsn
--startpos=lsn

In --start mode, start replication from the given LSN. For details on the effect of this, see the documentation in Chapter 47 and Section 51.3. Ignored in other modes.

--if-not-exists

Do not error out when --create-slot is specified and a slot with the specified name already exists.

-n
--no-loop

When the connection to the server is lost, do not retry in a loop, just exit.

-o name[=value]
--option=name[=value]

Pass the option name to the output plugin with, if specified, the option value value. Which options exist and their effects depends on the used output plugin.

-P plugin
--plugin=plugin

When creating a slot, use the specified logical decoding output plugin. See Chapter 47. This option has no effect if the slot already exists.

-s interval_seconds
--status-interval=interval_seconds

This option has the same effect as the option of the same name in pg_receivexlog. See the description there.

-S slot_name
--slot=slot_name

In --start mode, use the existing logical replication slot named slot_name. In --create-slot mode, create the slot with this name. In --drop-slot mode, delete the slot with this name.

-v
--verbose

Enables verbose mode.

The following command-line options control the database connection parameters.
pg_recvlogical

-d database
--dbname=database

The database to connect to. See the description of the actions for what this means in detail. This can be a libpq connection string; see Section 32.1.1 for more information. Defaults to user name.

-h hostname-or-ip
--host=hostname-or-ip

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U user
--username=user

User name to connect as. Defaults to current operating system user name.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_recvlogical to prompt for a password before connecting to a database.

This option is never essential, since pg_recvlogical will automatically prompt for a password if the server demands password authentication. However, pg_recvlogical will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

The following additional options are available:

-V
--version

Print the pg_recvlogical version and exit.

-?
--help

Show help about pg_recvlogical command line arguments, and exit.

Environment

This utility, like most other PostgreSQL utilities, uses the environment variables supported by libpq (see Section 32.14).
Examples
See Section 47.1 for an example.

pg_receivexlog
**pg_restore**

**Name**

`pg_restore` — restore a PostgreSQL database from an archive file created by `pg_dump`

**Synopsis**

`pg_restore [connection-option...] [option...] [filename]`

**Description**

`pg_restore` is a utility for restoring a PostgreSQL database from an archive created by `pg_dump` in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow `pg_restore` to be selective about what is restored, or even to reorder the items prior to being restored. The archive files are designed to be portable across architectures.

`pg_restore` can operate in two modes. If a database name is specified, `pg_restore` connects to that database and restores archive contents directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. This script output is equivalent to the plain text output format of `pg_dump`. Some of the options controlling the output are therefore analogous to `pg_dump` options.

Obviously, `pg_restore` cannot restore information that is not present in the archive file. For instance, if the archive was made using the "dump data as INSERT commands" option, `pg_restore` will not be able to load the data using `COPY` statements.

**Options**

`pg_restore` accepts the following command line arguments.

- `filename`
  - Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.
- `-a`
- `--data-only`
  - Restore only the data, not the schema (data definitions). Table data, large objects, and sequence values are restored, if present in the archive.
  - This option is similar to, but for historical reasons not identical to, specifying `--section=data`.
- `-c`
- `--clean`
  - Clean (drop) database objects before recreating them. (Unless `--if-exists` is used, this might generate some harmless error messages, if any objects were not present in the destination database.)
-c
--create

Create the database before restoring into it. If --clean is also specified, drop and recreate the target database before connecting to it.

When this option is used, the database named with -d is used only to issue the initial DROP DATABASE and CREATE DATABASE commands. All data is restored into the database name that appears in the archive.

-d dbname
--dbname=dbname

Connect to database dbname and restore directly into the database.

-e
--exit-on-error

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

-f filename
--file=filename

Specify output file for generated script, or for the listing when used with -l. Default is the standard output.

-F format
--format=format

Specify format of the archive. It is not necessary to specify the format, since pg_restore will determine the format automatically. If specified, it can be one of the following:

c
  custom

  The archive is in the custom format of pg_dump.

d
  directory

  The archive is a directory archive.

t
  tar

  The archive is a tar archive.

-I index
--index=index

Restore definition of named index only. Multiple indexes may be specified with multiple -I switches.

-j number-of-jobs
--jobs=number-of-jobs

Run the most time-consuming parts of pg_restore — those which load data, create indexes, or create constraints — using multiple concurrent jobs. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.
The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom and directory archive formats are supported with this option. The input must be a regular file or directory (not, for example, a pipe). This option is ignored when emitting a script rather than connecting directly to a database server. Also, multiple jobs cannot be used together with the option `--single-transaction`.

- `l`  
  `--list`  
  List the contents of the archive. The output of this operation can be used as input to the `-L` option. Note that if filtering switches such as `-n` or `-t` are used with `-l`, they will restrict the items listed.

- `-L` `list-file`  
  `--use-list=list-file`  
  Restore only those archive elements that are listed in `list-file`, and restore them in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

  `list-file` is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (`;`) at the start of the line. See below for examples.

- `-n` `namespace`  
  `--schema=namespace`  
  Restore only objects that are in the named schema. Multiple schemas may be specified with multiple `-n` switches. This can be combined with the `-t` option to restore just a specific table.

- `-O`  
  `--no-owner`  
  Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-O`, any user name can be used for the initial connection, and this user will own all the created objects.

- `-P` `function-name(argtype [, ...])`  
  `--function=function-name(argtype [, ...])`  
  Restore the named function only. Be careful to spell the function name and arguments exactly as they appear in the dump file’s table of contents. Multiple functions may be specified with multiple `-P` switches.

- `-R`  
  `--no-reconnect`  
  This option is obsolete but still accepted for backwards compatibility.

- `-s`  
  `--schema-only`  
  Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.
This option is the inverse of --data-only. It is similar to, but for historical reasons not identical to, specifying --section=pre-data --section=post-data.

(Do not confuse this with the --schema option, which uses the word “schema” in a different meaning.)

-S username
--superuser=username

Specify the superuser user name to use when disabling triggers. This is relevant only if --disable-triggers is used.

-t table
--table=table

Restore definition and/or data of only the named table. For this purpose, “table” includes views, materialized views, sequences, and foreign tables. Multiple tables can be selected by writing multiple -t switches. This option can be combined with the -n option to specify table(s) in a particular schema.

Note: When -t is specified, pg_restore makes no attempt to restore any other database objects that the selected table(s) might depend upon. Therefore, there is no guarantee that a specific-table restore into a clean database will succeed.

Note: This flag does not behave identically to the -t flag of pg_dump. There is not currently any provision for wild-card matching in pg_restore, nor can you include a schema name within its -t.

Note: In versions prior to PostgreSQL 9.6, this flag matched only tables, not any other type of relation.

-T trigger
--trigger=trigger

Restore named trigger only. Multiple triggers may be specified with multiple -T switches.

-v
--verbose

Specifies verbose mode.

-V
--version

Print the pg_restore version and exit.

-x
--no-privileges
--no-acl

Prevent restoration of access privileges (grant/revoke commands).
pg_restore

-1

--single-transaction

Execute the restore as a single transaction (that is, wrap the emitted commands in BEGIN/COMMIT). This ensures that either all the commands complete successfully, or no changes are applied. This option implies --exit-on-error.

--disable-triggers

This option is relevant only when performing a data-only restore. It instructs pg_restore to execute commands to temporarily disable triggers on the target tables while the data is reloaded. Use this if you have referential integrity checks or other triggers on the tables that you do not want to invoke during data reload.

Presently, the commands emitted for --disable-triggers must be done as superuser. So you should also specify a superuser name with -S or, preferably, run pg_restore as a PostgreSQL superuser.

--enable-row-security

This option is relevant only when restoring the contents of a table which has row security. By default, pg_restore will set row_security to off, to ensure that all data is restored in to the table. If the user does not have sufficient privileges to bypass row security, then an error is thrown. This parameter instructs pg_restore to set row_security to on instead, allowing the user to attempt to restore the contents of the table with row security enabled. This might still fail if the user does not have the right to insert the rows from the dump into the table.

Note that this option currently also requires the dump be in INSERT format, as COPY FROM does not support row security.

--if-exists

Use conditional commands (i.e. add an IF EXISTS clause) when cleaning database objects. This option is not valid unless --clean is also specified.

--no-data-for-failed-tables

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful if the target database already contains the desired table contents. For example, auxiliary tables for PostgreSQL extensions such as PostGIS might already be loaded in the target database; specifying this option prevents duplicate or obsolete data from being loaded into them.

This option is effective only when restoring directly into a database, not when producing SQL script output.

--no-security-labels

Do not output commands to restore security labels, even if the archive contains them.

--no-tablespaces

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

--section=sectionname

Only restore the named section. The section name can be pre-data, data, or post-data. This option can be specified more than once to select multiple sections. The default is to restore all sections.
The data section contains actual table data as well as large-object definitions. Post-data items consist of definitions of indexes, triggers, rules and constraints other than validated check constraints. Pre-data items consist of all other data definition items.

--strict-names

Require that each schema (-n/--schema) and table (-t/--table) qualifier match at least one schema/table in the backup file.

--use-set-session-authorization

Output SQL-standard SET SESSION AUTHORIZATION commands instead of ALTER OWNER commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, might not restore properly.

-?
--help

Show help about pg_restore command line arguments, and exit.

pg_restore also accepts the following command line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket. The default is taken from the PGHOST environment variable, if set, else a Unix domain socket connection is attempted.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections. Defaults to the PGPORT environment variable, if set, or a compiled-in default.

-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force pg_restore to prompt for a password before connecting to a database.

This option is never essential, since pg_restore will automatically prompt for a password if the server demands password authentication. However, pg_restore will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--role=rolename

Specifies a role name to be used to perform the restore. This option causes pg_restore to issue a SET ROLE rolename command after connecting to the database. It is useful when the authenticated user (specified by -U) lacks privileges needed by pg_restore, but can switch to a role with
the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

Environment

PGHOST
PGOPTIONS
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14). However, it does not read PGDATABASE when a database name is not supplied.

Diagnostics

When a direct database connection is specified using the -d option, pg_restore internally executes SQL statements. If you have problems running pg_restore, make sure you are able to select information from the database using, for example, psql. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

If your installation has any local additions to the template1 database, be careful to load the output of pg_restore into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from template0 not template1, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

The limitations of pg_restore are detailed below.

• When restoring data to a pre-existing table and the option --disable-triggers is used, pg_restore emits commands to disable triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs might be left in the wrong state.

• pg_restore cannot restore large objects selectively; for instance, only those for a specific table. If an archive contains large objects, then all large objects will be restored, or none of them if they are excluded via -L, -t, or other options.

See also the pg_dump documentation for details on limitations of pg_dump.

Once restored, it is wise to run ANALYZE on each restored table so the optimizer has useful statistics; see Section 24.1.3 and Section 24.1.6 for more information.
Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
$ pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
$ dropdb mydb
$ pg_restore -C -d postgres db.dump
```

The database named in the `-d` switch can be any database existing in the cluster; `pg_restore` only uses it to issue the `CREATE DATABASE` command for `mydb`. With `-C`, data is always restored into the database name that appears in the dump file.

To reload the dump into a new database called `newdb`:

```
$ createdb -T template0 newdb
$ pg_restore -d newdb db.dump
```

Notice we don’t use `-C`, and instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty.

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
$ pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, e.g.:

```
; Archive created at Mon Sep 14 13:55:39 2009
; dbname: DBDEMONS
; TOC Entries: 81
; Compression: 9
; Dump Version: 1.10-0
; Format: CUSTOM
; Integer: 4 bytes
; Offsets: 8 bytes
; Dumped from database version: 8.3.5
; Dumped by pg_dump version: 8.3.8
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item.

Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
```
could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
$ pg_restore -L db.list db.dump
```

psql

Name

psql — PostgreSQL interactive terminal

Synopsis

psql [option...] [dbname [username]]

Description

psql is a terminal-based front-end to PostgreSQL. It enables you to type in queries interactively, issue them to PostgreSQL, and see the query results. Alternatively, input can be from a file or from command line arguments. In addition, psql provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

Options

-a
--echo-all

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable ECHO to all.

-A
--no-align

Switches to unaligned output mode. (The default output mode is otherwise aligned.)

-b
--echo-errors

Print failed SQL commands to standard error output. This is equivalent to setting the variable ECHO to errors.

-c command
--command=command

Specifies that psql is to execute the given command string, command. This option can be repeated and combined in any order with the -f option. When either -c or -f is specified, psql does not read commands from standard input; instead it terminates after processing all the -c and -f options in sequence.

c command must be either a command string that is completely parsable by the server (i.e., it contains no psql-specific features), or a single backslash command. Thus you cannot mix SQL and psql meta-commands within a -c option. To achieve that, you could use repeated -c options or pipe the string into psql, for example:

psql -c ‘\x’ -c ‘SELECT * FROM foo;’
or
echo ‘\x \ SELECT * FROM foo;’ | psql
(\ is the separator meta-command.)

Each SQL command string passed to \-c is sent to the server as a single query. Because of this, the server executes it as a single transaction even if the string contains multiple SQL commands, unless there are explicit BEGIN/COMMIT commands included in the string to divide it into multiple transactions. Also, psql only prints the result of the last SQL command in the string. This is different from the behavior when the same string is read from a file or fed to psql’s standard input, because then psql sends each SQL command separately.

Because of this behavior, putting more than one command in a single \-c string often has unexpected results. It’s better to use repeated \-c commands or feed multiple commands to psql’s standard input, either using echo as illustrated above, or via a shell here-document, for example:

```bash
psql <<EOF
\x
SELECT * FROM foo;
EOF
-d dbname
--dbname=dbname

Specifies the name of the database to connect to. This is equivalent to specifying dbname as the first non-option argument on the command line.

If this parameter contains an = sign or starts with a valid URI prefix (postgresql:// or postgres://), it is treated as a conninfo string. See Section 32.1.1 for more information.

-e
--echo-queries

Copy all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries.

-E
--echo-hidden

Echo the actual queries generated by \d and other backslash commands. You can use this to study psql’s internal operations. This is equivalent to setting the variable ECHO_HIDDEN to on.

-f filename
--file=filename

Read commands from the file filename, rather than standard input. This option can be repeated and combined in any order with the \-c option. When either \-c or \-f is specified, psql does not read commands from standard input; instead it terminates after processing all the \-c and \-f options in sequence. Except for that, this option is largely equivalent to the meta-command \i.

If filename is - (hyphen), then standard input is read until an EOF indication or \q meta-command. This can be used to intersperse interactive input with input from files. Note however that Readline is not used in this case (much as if \-n had been specified).

Using this option is subtly different from writing psql < filename. In general, both will do what you expect, but using \-f enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell’s input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

-F separator
--field-separator=separator

Use separator as the field separator for unaligned output. This is equivalent to \pset fieldsep or \f.

1852
- h hostname
--host=hostname

Specifies the host name of the machine on which the server is running. If the value begins with a
slash, it is used as the directory for the Unix-domain socket.

- H
--html

Turn on HTML tabular output. This is equivalent to \pset format html or the \H command.

- l
--list

List all available databases, then exit. Other non-connection options are ignored. This is similar
to the meta-command \list.

- L filename
--log-file=filename

Write all query output into file filename, in addition to the normal output destination.

- n
--no-readline

Do not use Readline for line editing and do not use the command history. This can be useful to
turn off tab expansion when cutting and pasting.

- o filename
--output=filename

Put all query output into file filename. This is equivalent to the command \o.

- p port
--port=port

Specifies the TCP port or the local Unix-domain socket file extension on which the server is
listening for connections. Defaults to the value of the PGPORT environment variable or, if not set,
to the port specified at compile time, usually 5432.

- P assignment
--pset=assignment

Specifies printing options, in the style of \pset. Note that here you have to separate name and
value with an equal sign instead of a space. For example, to set the output format to LaTeX, you
could write -P format=latex.

- q
--quiet

Specifies that psql should do its work quietly. By default, it prints welcome messages and various
informational output. If this option is used, none of this happens. This is useful with the -c
option. This is equivalent to setting the variable QUIET to on.

- R separator
--record-separator=separator

Use separator as the record separator for unaligned output. This is equivalent to the \pset
recordsep command.
psql

-s
--single-step

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

-S
--single-line

Runs in single-line mode where a newline terminates an SQL command, as a semicolon does.

Note: This mode is provided for those who insist on it, but you are not necessarily encouraged to use it. In particular, if you mix SQL and meta-commands on a line the order of execution might not always be clear to the inexperienced user.

-t
--tuples-only

Turn off printing of column names and result row count footers, etc. This is equivalent to the \t command.

-T table_options
--table-attr=table_options

Specifies options to be placed within the HTML table tag. See \pset for details.

-U username
--username=username

Connect to the database as the user username instead of the default. (You must have permission to do so, of course.)

-v assignment
--set=assignment
--variable=assignment

Perform a variable assignment, like the \set meta-command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

-V
--version

Print the psql version and exit.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command \connect as well as the initial connection attempt.

-W
--password

Force psql to prompt for a password before connecting to a database.
This option is never essential, since psql will automatically prompt for a password if the server demands password authentication. However, psql will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing \-W to avoid the extra connection attempt.

Note that this option will remain set for the entire session, and so it affects uses of the meta-command \connect as well as the initial connection attempt.

-x
--expanded

Turn on the expanded table formatting mode. This is equivalent to the \x command.

-X,
--no-psqlrc

Do not read the start-up file (neither the system-wide psqlrc file nor the user’s ~/.psqlrc file).

-z
--field-separator-zero

Set the field separator for unaligned output to a zero byte.

-0
--record-separator-zero

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with xargs -0.

-1
--single-transaction

This option can only be used in combination with one or more -c and/or -f options. It causes psql to issue a BEGIN command before the first such option and a COMMIT command after the last one, thereby wrapping all the commands into a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the commands themselves contain BEGIN, COMMIT, or ROLLBACK, this option will not have the desired effects. Also, if an individual command cannot be executed inside a transaction block, specifying this option will cause the whole transaction to fail.

-?
--help[=topic]

Show help about psql and exit. The optional topic parameter (defaulting to options) selects which part of psql is explained: commands describes psql’s backslash commands; options describes the command-line options that can be passed to psql; and variables shows help about psql configuration variables.

**Exit Status**

psql returns 0 to the shell if it finished normally, 1 if a fatal error of its own occurs (e.g. out of memory, file not found), 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable ON_ERROR_STOP was set.
Usage

Connecting to a Database

psql is a regular PostgreSQL client application. In order to connect to a database you need to know the name of your target database, the host name and port number of the server, and what user name you want to connect as. psql can be told about those parameters via command line options, namely -d, -h, -p, and -U respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, psql will connect via a Unix-domain socket to a server on the local host, or via TCP/IP to localhost on machines that don’t have Unix-domain sockets. The default port number is determined at compile time. Since the database server uses the same default, you will not have to specify the port in most cases. The default user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults aren’t quite right, you can save yourself some typing by setting the environment variables PGDATABASE, PGHOST, PGPORT and/or PGUSER to appropriate values. (For additional environment variables, see Section 32.14.) It is also convenient to have a ~/.pgpass file to avoid regularly having to type in passwords. See Section 32.15 for more information.

An alternative way to specify connection parameters is in a conninfo string or a URI, which is used instead of a database name. This mechanism give you very wide control over the connection. For example:

$ psql "service=myservice sslmode=require"
$ psql postgresql://dbmaster:5433/mydb?sslmode=requir

This way you can also use LDAP for connection parameter lookup as described in Section 32.17. See Section 32.1.2 for more information on all the available connection options.

If the connection could not be made for any reason (e.g., insufficient privileges, server is not running on the targeted host, etc.), psql will return an error and terminate.

If both standard input and standard output are a terminal, then psql sets the client encoding to “auto”, which will detect the appropriate client encoding from the locale settings (LC_CTYPE environment variable on Unix systems). If this doesn’t work out as expected, the client encoding can be overridden using the environment variable PGCLIENTENCODING.

Entering SQL Commands

In normal operation, psql provides a prompt with the name of the database to which psql is currently connected, followed by the string =>. For example:

$ psql testdb
psql (9.6.13)
Type "help" for help.

testdb=>

At the prompt, the user can type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus
commands can be spread over several lines for clarity. If the command was sent and executed without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin your session by removing publicly-writable schemas from search_path. One can add options=-csearch_path= to the connection string or issue SELECT pg_catalog.set_config('search_path', "", false) before other SQL commands. This consideration is not specific to psql; it applies to every interface for executing arbitrary SQL commands.

Whenever a command is executed, psql also polls for asynchronous notification events generated by LISTEN and NOTIFY.

While C-style block comments are passed to the server for processing and removal, SQL-standard comments are removed by psql.

Meta-Commands

Anything you enter in psql that begins with an unquoted backslash is a psql meta-command that is processed by psql itself. These commands make psql more useful for administration or scripting. Meta-commands are often called slash or backslash commands.

The format of a psql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace in an argument you can quote it with single quotes. To include a single quote in an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \b (backspace), \r (carriage return), \f (form feed), \d (octal), and \x (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

Within an argument, text that is enclosed in backquotes (`) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text.

If an unquoted colon (:) followed by a psql variable name appears within an argument, it is replaced by the variable’s value, as described in SQL Interpolation.

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird" " name" becomes A weird" name.

Parsing for arguments stops at the end of the line, or when another unquoted backslash is found. An unquoted backslash is taken as the beginning of a new meta-command. The special sequence \ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and psql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

\a

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See \pset for a more general solution.
\connect [ -reuse-previous-on|off ] [ dbname [ username ] [ host ] [ port ] ] | conninfo |

Establishes a new connection to a PostgreSQL server. The connection parameters to use can be specified either using a positional syntax, or using conninfo connection strings as detailed in Section 32.1.1.

Where the command omits database name, user, host, or port, the new connection can reuse values from the previous connection. By default, values from the previous connection are reused except when processing a conninfo string. Passing a first argument of -reuse-previous-on or -reuse-previous-off overrides that default. When the command neither specifies nor reuses a particular parameter, the libpq default is used. Specifying any of dbname, username, host or port as - is equivalent to omitting that parameter.

If the new connection is successfully made, the previous connection is closed. If the connection attempt failed (wrong user name, access denied, etc.), the previous connection will only be kept if psql is in interactive mode. When executing a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos on the one hand, and a safety mechanism that scripts are not accidentally acting on the wrong database on the other hand.

Examples:
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c postgresql://tom@localhost/mydb?application_name=myapp

\C [ title ]

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to \pset title title. (The name of this command derives from “caption”, as it was previously only used to set the caption in an HTML table.)

\cd [ directory ]

Changes the current working directory to directory. Without argument, changes to the current user’s home directory.

Tip: To print your current working directory, use \! pwd.

\conninfo

Outputs information about the current database connection.

\copy { table [ ( column_list ) ] | ( query ) } { from | to } { 'filename' | program 'command' | stdin | stdout | pstdin | pstdout } [ [ with ] ( option [, ...] ) ]

Performs a frontend (client) copy. This is an operation that runs an SQL COPY command, but instead of the server reading or writing the specified file, psql reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When program is specified, command is executed by psql and the data passed from or to command is routed between the server and the client. Again, the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.
For \copy ... from stdin, data rows are read from the same source that issued the command, continuing until \. is read or the stream reaches EOF. This option is useful for populating tables in-line within a SQL script file. For \copy ... to stdout, output is sent to the same place as psql command output, and the COPY count command status is not printed (since it might be confused with a data row). To read/write psql’s standard input or output regardless of the current command source or \o option, write from pstdin or to pstdout.

The syntax of this command is similar to that of the SQL COPY command. All options other than the data source/destination are as specified for COPY. Because of this, special parsing rules apply to the \copy command. In particular, psql’s variable substitution rules and backslash escapes do not apply.

Tip: Another way to obtain the same result as \copy ... to is to use the SQL COPY ... TO STDOUT command and terminate it with \g filename or \g | program. Unlike \copy, this method allows the command to span multiple lines; also, variable interpolation and backquote expansion can be used.

Tip: These operations are not as efficient as the SQL COPY command with a file or program data source or destination, because all data must pass through the client/server connection. For large amounts of data the SQL command might be preferable.

\copyright

Shows the copyright and distribution terms of PostgreSQL.

Executes the current query buffer (like \g) and shows the results in a crosstab grid. The query must return at least three columns. The output column identified by colV becomes a vertical header and the output column identified by colH becomes a horizontal header. colD identifies the output column to display within the grid. sortcolH identifies an optional sort column for the horizontal header.

Each column specification can be a column number (starting at 1) or a column name. The usual SQL case folding and quoting rules apply to column names. If omitted, colV is taken as column 1 and colH as column 2. colH must differ from colV. If colD is not specified, then there must be exactly three columns in the query result, and the column that is neither colV nor colH is taken to be colD.

The vertical header, displayed as the leftmost column, contains the values found in column colV, in the same order as in the query results, but with duplicates removed.

The horizontal header, displayed as the first row, contains the values found in column colH, with duplicates removed. By default, these appear in the same order as in the query results. But if the optional sortcolH argument is given, it identifies a column whose values must be integer numbers, and the values from colH will appear in the horizontal header sorted according to the corresponding sortcolH values.

Inside the crosstab grid, for each distinct value x of colH and each distinct value y of colV, the cell located at the intersection (x, y) contains the value of the colD column in the query result row for which the value of colH is x and the value of colV is y. If there is no such row, the cell is empty. If there are multiple such rows, an error is reported.
\d\[S+\] [ pattern ]

For each relation (table, view, materialized view, index, sequence, or foreign table) or composite type matching the pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as NOT NULL or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well. (“Matching the pattern” is defined in Patterns below.)

For some types of relation, \d shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.

The command form \d+ is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view, a non-default replica identity setting.

By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects.

**Note:** If \d is used without a pattern argument, it is equivalent to \d\vtvmsE which will show a list of all visible tables, views, materialized views, sequences and foreign tables. This is purely a convenience measure.

\da\[S\] [ pattern ]

Lists aggregate functions, together with their return type and the data types they operate on. If pattern is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects.

\d\[A+\] [ pattern ]

Lists access methods. If pattern is specified, only access methods whose names match the pattern are shown. If + is appended to the command name, each access method is listed with its associated handler function and description.

\db\[+\] [ pattern ]

Lists tablespaces. If pattern is specified, only tablespaces whose names match the pattern are shown. If + is appended to the command name, each tablespace is listed with its associated options, on-disk size, permissions and description.

\dc\[S+\] [ pattern ]

Lists conversions between character-set encodings. If pattern is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the $S$ modifier to include system objects. If + is appended to the command name, each object is listed with its associated description.

\d\[C+\] [ pattern ]

Lists type casts. If pattern is specified, only casts whose source or target types match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

\dd\[S\] [ pattern ]

Shows the descriptions of objects of type constraint, operator class, operator family, rule, and trigger. All other comments may be viewed by the respective backslash commands for those object types.
\dd displays descriptions for objects matching the pattern, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a description are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

Descriptions for objects can be created with the COMMENT SQL command.

\ddp [ pattern ]

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If pattern is specified, only entries whose role name or schema name matches the pattern are listed.

The ALTER DEFAULT PRIVILEGES command is used to set default access privileges. The meaning of the privilege display is explained under GRANT.

\dD[S+] [ pattern ]

Lists domains. If pattern is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects. If + is appended to the command name, each object is listed with its associated permissions and description.

\dE[S+] [ pattern ]
\di[S+] [ pattern ]
\dm[S+] [ pattern ]
\ds[S+] [ pattern ]
\dt[S+] [ pattern ]
\dv[S+] [ pattern ]

In this group of commands, the letters E, i, m, s, t, and v stand for foreign table, index, materialized view, sequence, table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, \dit lists indexes and tables. If + is appended to the command name, each object is listed with its physical size on disk and its associated description, if any. If pattern is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the S modifier to include system objects.

\des[+] [ pattern ]

Lists foreign servers (mnemonic: "external servers"). If pattern is specified, only those servers whose name matches the pattern are listed. If the form \des+ is used, a full description of each server is shown, including the server’s ACL, type, version, options, and description.

\det[+] [ pattern ]

Lists foreign tables (mnemonic: “external tables”). If pattern is specified, only entries whose table name or schema name matches the pattern are listed. If the form \det+ is used, generic options and the foreign table description are also displayed.

\deu[+] [ pattern ]

Lists user mappings (mnemonic: “external users”). If pattern is specified, only those mappings whose user names match the pattern are listed. If the form \deu+ is used, additional information about each mapping is shown.

Caution
\deu+ might also display the user name and password of the remote user, so care should be taken not to disclose them.
psql

\dew[+]+ [ pattern ]

Lists foreign-data wrappers (mnemonic: “external wrappers”). If pattern is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form \dew+ is used, the ACL, options, and description of the foreign-data wrapper are also shown.

\df[antwST]+ [ pattern ]

Lists functions, together with their result data types, argument data types, and function types, which are classified as “agg” (aggregate), “normal”, “trigger”, or “window”. To display only functions of specific type(s), add the corresponding letters a, n, t, or w to the command. If pattern is specified, only functions whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the $ modifier to include system objects. If the form \df+ is used, additional information about each function is shown, including volatility, parallel safety, owner, security classification, access privileges, language, source code and description.

**Tip:** To look up functions taking arguments or returning values of a specific data type, use your pager’s search capability to scroll through the \df output.

\dF[+]+ [ pattern ]

Lists text search configurations. If pattern is specified, only configurations whose names match the pattern are shown. If the form \dF+ is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

\dFd[+]+ [ pattern ]

Lists text search dictionaries. If pattern is specified, only dictionaries whose names match the pattern are shown. If the form \dFd+ is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

\dFp[+]+ [ pattern ]

Lists text search parsers. If pattern is specified, only parsers whose names match the pattern are shown. If the form \dFp+ is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

\dFt[+]+ [ pattern ]

Lists text search templates. If pattern is specified, only templates whose names match the pattern are shown. If the form \dFt+ is used, additional information is shown about each template, including the underlying function names.

\dg[S]+ [ pattern ]

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”, this command is now equivalent to \du.) By default, only user-created roles are shown; supply the $ modifier to include system roles. If pattern is specified, only those roles whose names match the pattern are listed. If the form \dg+ is used, additional information is shown about each role; currently this adds the comment for each role.

\dl

This is an alias for \lo_list, which shows a list of large objects.

\dL[S]+ [ pattern ]

Lists procedural languages. If pattern is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the $ modifier to
include system objects. If + is appended to the command name, each language is listed with its
call handler, validator, access privileges, and whether it is a system object.

\dn[S+] [ pattern ]

Lists schemas (namespaces). If pattern is specified, only schemas whose names match the
pattern are listed. By default, only user-created objects are shown; supply a pattern or the S
modifier to include system objects. If + is appended to the command name, each object is listed
with its associated permissions and description, if any.

\do[S+] [ pattern ]

Lists operators with their operand and result types. If pattern is specified, only operators whose
names match the pattern are listed. By default, only user-created objects are shown; supply a
pattern or the S modifier to include system objects. If + is appended to the command name,
additional information about each operator is shown, currently just the name of the underlying
function.

\dO[S+] [ pattern ]

Lists collations. If pattern is specified, only collations whose names match the pattern are
listed. By default, only user-created objects are shown; supply a pattern or the S modifier to
include system objects. If + is appended to the command name, each collation is listed with
its associated description, if any. Note that only collations usable with the current database’s
encoding are shown, so the results may vary in different databases of the same installation.

\dp [ pattern ]

Lists tables, views and sequences with their associated access privileges. If pattern is specified,
only tables, views and sequences whose names match the pattern are listed.

The GRANT and REVOKE commands are used to set access privileges. The meaning of the
privilege display is explained under GRANT.

\drds [ role-pattern [ database-pattern ] ]

Lists defined configuration settings. These settings can be role-specific, database-specific, or
both. role-pattern and database-pattern are used to select specific roles and databases
to list, respectively. If omitted, or if * is specified, all settings are listed, including those not
role-specific or database-specific, respectively.

The ALTER ROLE and ALTER DATABASE commands are used to define per-role and per-
database configuration settings.

\dT[S+] [ pattern ]

Lists data types. If pattern is specified, only types whose names match the pattern are listed.
If + is appended to the command name, each type is listed with its internal name and size, its
allowed values if it is an enum type, and its associated permissions. By default, only user-created
objects are shown; supply a pattern or the S modifier to include system objects.

\du[S+] [ pattern ]

Lists database roles. (Since the concepts of “users” and “groups” have been unified into “roles”,
this command is now equivalent to \dg.) By default, only user-created roles are shown; supply
the S modifier to include system roles. If pattern is specified, only those roles whose names
match the pattern are listed. If the form \du+ is used, additional information is shown about each
role; currently this adds the comment for each role.

\dx[+] [ pattern ]

Lists installed extensions. If pattern is specified, only those extensions whose names match the
pattern are listed. If the form \dx+ is used, all the objects belonging to each matching extension
are listed.
\dy[+] [ pattern ]

Lists event triggers. If pattern is specified, only those event triggers whose names match the pattern are listed. If + is appended to the command name, each object is listed with its associated description.

\e or \edit [ filename ] [ line_number ]

If filename is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no filename is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of psql, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) This means that if the query ends with (or contains) a semicolon, it is immediately executed. Otherwise it will merely wait in the query buffer; type semicolon or \g to send it, or \r to cancel.

If a line number is specified, psql will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, psql assumes it is a line number, not a file name.

Tip: See under Environment for how to configure and customize your editor.

\echo text [ ... ]

Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. For example:

```
=> \echo 'date'
Tue Oct 26 21:40:57 CEST 1999
```

If the first argument is an unquoted -n the trailing newline is not written.

Tip: If you use the \o command to redirect your query output you might wish to use \qecho instead of this command.

\ef [ function_description [ line_number ] ]

This command fetches and edits the definition of the named function, in the form of a CREATE OR REPLACE FUNCTION command. Editing is done in the same way as for \edit. After the editor exits, the updated command waits in the query buffer; type semicolon or \g to send it, or \r to cancel.

The target function can be specified by name alone, or by name and arguments, for example foo(integer, text). The argument types must be given if there is more than one function of the same name.

If no function is specified, a blank CREATE FUNCTION template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

Tip: See under Environment for how to configure and customize your editor.
\encoding [ encoding ]

Sets the client character set encoding. Without an argument, this command shows the current
encoding.

\errverbose

Repeats the most recent server error message at maximum verbosity, as though VERBOSITY were
set to verbose and SHOW_CONTEXT were set to always.

\ev [ view_name [ line_number ] ]

This command fetches and edits the definition of the named view, in the form of a CREATE OR
REPLACE VIEW command. Editing is done in the same way as for \edit. After the editor exits,
the updated command waits in the query buffer; type semicolon or \g to send it, or \r to cancel.

If no view is specified, a blank CREATE VIEW template is presented for editing.

If a line number is specified, psql will position the cursor on the specified line of the view
definition.

\f [ string ]

Sets the field separator for unaligned query output. The default is the vertical bar (|). See also
\pset for a generic way of setting output options.

\g [ filename ]

\g [ |command ]

Sends the current query input buffer to the server, and optionally stores the query’s output in
filename or pipes the output to the shell command command. The file or command is written
to only if the query successfully returns zero or more tuples, not if the query fails or is a non-
data-returning SQL command.

A bare \g is essentially equivalent to a semicolon. A \g with argument is a “one-shot” alternative
to the \o command.

\gexec

Sends the current query input buffer to the server, then treats each column of each row of the
query’s output (if any) as a SQL statement to be executed. For example, to create an index on
each column of my_table:

```sql
-> SELECT format('create index on my_table(%I)', attname)
-> FROM pg_attribute
-> WHERE attrelid = 'my_table'::regclass AND attnum > 0
-> ORDER BY attnum
-> \gexec
CREATE INDEX
CREATE INDEX
CREATE INDEX
CREATE INDEX
```

The generated queries are executed in the order in which the rows are returned, and left-to-right
within each row if there is more than one column. NULL fields are ignored. The generated
queries are sent literally to the server for processing, so they cannot be psql meta-commands
nor contain psql variable references. If any individual query fails, execution of the remaining
queries continues unless ON_ERROR_STOP is set. Execution of each query is subject to ECHO
processing. (Setting ECHO to all or queries is often advisable when using \gexec.) Query
logging, single-step mode, timing, and other query execution features apply to each generated
query as well.
\gset [ prefix ]

Sends the current query input buffer to the server and stores the query’s output into psql variables (see Variables). The query to be executed must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2
=> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a prefix, that string is prepended to the query’s column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2
=> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

\h or \help [ command ]

Gives syntax help on the specified SQL command. If command is not specified, then psql will list all the commands for which syntax help is available. If command is an asterisk (*), then syntax help on all SQL commands is shown.

**Note:** To simplify typing, commands that consists of several words do not have to be quoted. Thus it is fine to type `\help alter table`.

\H or \html

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see \pset about setting other output options.

\i or \include filename

Reads input from the file filename and executes it as though it had been typed on the keyboard. If filename is - (hyphen), then standard input is read until an EOF indication or \q metacommand. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

**Note:** If you want to see the lines on the screen as they are read you must set the variable ECHO to all.

\ir or \include_relative filename

The \ir command is similar to \i, but resolves relative file names differently. When executing in interactive mode, the two commands behave identically. However, when invoked from a script, \ir interprets file names relative to the directory in which the script is located, rather than the current working directory.
List the databases in the server and show their names, owners, character set encodings, and access privileges. If *pattern* is specified, only databases whose names match the pattern are listed. If + is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

**\lo_export loid filename**

Reads the large object with OID *loid* from the database and writes it to *filename*. Note that this is subtly different from the server function *lo_export*, which acts with the permissions of the user that the database server runs as and on the server’s file system.

**Tip:** Use \lo_list to find out the large object’s OID.

**\lo_import filename [ comment ]**

Stores the file into a PostgreSQL large object. Optionally, it associates the given comment with the object. Example:

```
foo-> \lo_import '/home/peter/pictures/photo.xcf' 'a picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801, which can be used to access the newly-created large object in the future. For the sake of readability, it is recommended to always associate a human-readable comment with every object. Both OIDs and comments can be viewed with the \lo_list command.

Note that this command is subtly different from the server-side *lo_import* because it acts as the local user on the local file system, rather than the server’s user and file system.

**\lo_list**

Shows a list of all PostgreSQL large objects currently stored in the database, along with any comments provided for them.

**\lo_unlink loid**

Deletes the large object with OID *loid* from the database.

**Tip:** Use \lo_list to find out the large object’s OID.

**\o or \out [ filename ]**

**\o or \out [ |command |**

Arranges to save future query results to the file *filename* or pipe future results to the shell command *command*. If no argument is specified, the query output is reset to the standard output. “Query results” includes all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as \d), but not error messages.

**Tip:** To intersperse text output between query results, use \qecho.

**\p or \print**

Print the current query buffer to the standard output.
\password [ username ]

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an ALTER ROLE command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

\prompt [ text ] name

Prompts the user to supply text, which is assigned to the variable name. An optional prompt string, text, can be specified. (For multiword prompts, surround the text with single quotes.) By default, \prompt uses the terminal for input and output. However, if the -f command line switch was used, \prompt uses standard input and standard output.

\pset [ option [ value ] ]

This command sets options affecting the output of query result tables. option indicates which option is to be set. The semantics of value vary depending on the selected option. For some options, omitting value causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting value just results in the current setting being displayed.

\pset without any arguments displays the current status of all printing options.

Adjustable printing options are:

border

The value must be a number. In general, the higher the number the more borders and lines the tables will have, but details depend on the particular format. In HTML format, this will translate directly into the border=... attribute. In most other formats only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense, and values above 2 will be treated the same as border = 2. The latex and latex-longtable formats additionally allow a value of 3 to add dividing lines between data rows.

columns

Sets the target width for the wrapped format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. Zero (the default) causes the target width to be controlled by the environment variable COLUMNS, or the detected screen width if COLUMNS is not set. In addition, if columns is zero then the wrapped format only affects screen output. If columns is nonzero then file and pipe output is wrapped to that width as well.

expanded (or x)

If value is specified it must be either on or off, which will enable or disable expanded mode, or auto. If value is omitted the command toggles between the on and off settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn’t fit on the screen in the normal “horizontal” mode. In the auto setting, the expanded mode is used whenever the query output has more than one column and is wider than the screen; otherwise, the regular mode is used. The auto setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is off.

fieldsep

Specifies the field separator to be used in unaligned output format. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a
tab as field separator, type `\pset fieldsep \t`. The default field separator is `|` (a vertical bar).

**fieldsep_zero**

Sets the field separator to use in unaligned output format to a zero byte.

**footer**

If `value` is specified it must be either `on` or `off` which will enable or disable display of the table footer (the `(n rows)` count). If `value` is omitted the command toggles footer display on or off.

**format**

Sets the output format to one of `unaligned`, `aligned`, `wrapped`, `html`, `asciidoc`, `latex` (uses `tabular`), `latex-longtable`, or `troff-ms`. Unique abbreviations are allowed.

`unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

`wrapped` format is like `aligned` but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that psql will not attempt to wrap column header titles; therefore, `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

The `html`, `asciidoc`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! This might not be necessary in HTML, but in LaTeX you must have a complete document wrapper. `latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.

**linestyle**

Sets the border line drawing style to one of `ascii`, `old-ascii`, or `unicode`. Unique abbreviations are allowed. (That would mean one letter is enough.) The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` style uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the `wrapped` format wraps data from one line to the next without a newline character, a dot (.) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, the `linestyle` option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.
null

Sets the string to be printed in place of a null value. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'.

numericlocale

If value is specified it must be either on or off which will enable or disable display of a locale-specific character to separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.

pager

Controls use of a pager program for query and psql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used.

When the pager option is off, the pager program is not used. When the pager option is on, the pager is used when appropriate, i.e., when the output is to a terminal and will not fit on the screen. The pager option can also be set to always, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager without a value` toggles pager use on and off.

pager_min_lines

If pager_min_lines is set to a number greater than the page height, the pager program will not be called unless there are at least this many lines of output to show. The default setting is 0.

recordsep

Specifies the record (line) separator to use in unaligned output format. The default is a newline character.

recordsep_zero

Sets the record separator to use in unaligned output format to a zero byte.

tableattr (or T)

In HTML format, this specifies attributes to be placed inside the table tag. This could for example be cellpadding or bgcolor. Note that you probably don’t want to specify border here, as that is already taken care of by `\pset border`. If no value is given, the table attributes are unset.

In latex-longtable format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g. ‘0.2 0.2 0.6’. Unspecified output columns use the last specified value.

title (or C)

Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title is unset.

tuples_only (or t)

If value is specified it must be either on or off which will enable or disable tuples-only mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown.
psql

unicode_border_linestyle

Sets the border drawing style for the unicode line style to one of single or double.

unicode_column_linestyle

Sets the column drawing style for the unicode line style to one of single or double.

unicode_header_linestyle

Sets the header drawing style for the unicode line style to one of single or double.

Illustrations of how these different formats look can be seen in the Examples section.

Tip: There are various shortcut commands for \pset. See \a, \C, \f, \H, \t, \T, and \x.

\q or \quit

Quits the psql program. In a script file, only execution of that script is terminated.

\qecho text [ ... ]

This command is identical to \echo except that the output will be written to the query output channel, as set by \o.

\r or \reset

Resets (clears) the query buffer.

\s [ filename ]

Print psql’s command line history to filename. If filename is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if psql was built without Readline support.

\set [ name [ value [ ... ] ] ]

Sets the psql variable name to value, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is set with an empty value. To unset a variable, use the \unset command.

\set without any arguments displays the names and values of all currently-set psql variables.

Valid variable names can contain letters, digits, and underscores. See the section Variables below for details. Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, psql treats several variables as special. They are documented in the section about variables.

Note: This command is unrelated to the SQL command SET.

\setenv name [ value ]

Sets the environment variable name to value, or if the value is not supplied, unsets the environment variable. Example:

testdb=> \setenv PAGER less

testdb=> \setenv LESS -imx4F
\sf[+] function_description

This command fetches and shows the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

\sv[+] view_name

This command fetches and shows the definition of the named view, in the form of a `CREATE OR REPLACE VIEW` command. The definition is printed to the current query output channel, as set by `\o`.

If `+` is appended to the command name, then the output lines are numbered from 1.

\t

Toggles the display of output column name headings and row count footer. This command is equivalent to `\pset tuples_only` and is provided for convenience.

\T table_options

Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`.

\timing [ on | off ]

Without parameter, toggles a display of how long each SQL statement takes, in milliseconds. With parameter, sets same.

\unset name

Unsets (deletes) the `psql` variable `name`.

\w or \write filename
\w or \write | command

Outputs the current query buffer to the file `filename` or pipes it to the shell command `command`.

\watch [ seconds ]

Repeatedly execute the current query buffer (as `\g` does) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions. Each query result is displayed with a header that includes the `\pset title` string (if any), the time as of query start, and the delay interval.

\x [ on | off | auto ]

Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

\z [ pattern ]

Lists tables, views and sequences with their associated access privileges. If a `pattern` is specified, only tables, views and sequences whose names match the pattern are listed.

This is an alias for `\dp ("display privileges")`. 

1872
Escapes to a separate shell or executes the shell command \texttt{command}. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

Shows help information. The optional \texttt{topic} parameter (defaulting to \texttt{commands}) selects which part of psql is explained: \texttt{commands} describes psql’s backslash commands; \texttt{options} describes the command-line options that can be passed to psql; and \texttt{variables} shows help about psql configuration variables.

Patterns

The various \texttt{\d} commands accept a \texttt{pattern} parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, \texttt{\d \textit{FOO}} will display the table named \textit{foo}. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, \texttt{\d "FOO""BAR"} will display the table named \textit{FOO"BAR} (not \textit{foo"bar}). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance \texttt{\d FOO"FOO"BAR} will display the table named \textit{fooFOObar}.

Whenever the \texttt{pattern} parameter is omitted completely, the \texttt{\d} commands display all objects that are visible in the current schema search path — this is equivalent to using \texttt{*} as the pattern. (An object is said to be \textit{visible} if its containing schema is in the search path and no object of the same kind and name appears earlier in the search path. This is equivalent to the statement that the object can be referenced by name without explicit schema qualification.) To see all objects in the database regardless of visibility, use \texttt{*.*} as the pattern.

Within a pattern, \texttt{*} matches any sequence of characters (including no characters) and \texttt{?} matches any single character. (This notation is comparable to Unix shell file name patterns.) For example, \texttt{\d \textit{int}*} displays tables whose names begin with \textit{int}. But within double quotes, \texttt{*} and \texttt{?} lose these special meanings and are just matched literally.

A pattern that contains a dot (\texttt{.}) is interpreted as a schema name pattern followed by an object name pattern. For example, \texttt{\d \textit{foo}*.\textit{bar}*} displays all tables whose table name includes \textit{bar} that are in schemas whose schema name starts with \textit{foo}. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations such as character classes, for example \texttt{[0-9]} to match any digit. All regular expression special characters work as specified in Section 9.7.3, except for \texttt{.} which is taken as a separator as mentioned above, \texttt{*} which is translated to the regular-expression notation \texttt{.*}, \texttt{?} which is translated to \texttt{.*}, and \texttt{\$} which is matched literally. You can emulate these pattern characters at need by writing \texttt{?} for \texttt{.*}, \texttt{(R+)} for \texttt{R*}, or \texttt{(R|)} for \texttt{R?}. \texttt{\$} is not needed as a regular-expression character since the pattern must match the whole name, unlike the usual interpretation of regular expressions (in other words, \texttt{\$} is automatically appended to your pattern). Write \texttt{*} at the beginning and/or end if you don’t wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (i.e., the argument of \texttt{\do}).
Advanced Features

Variables

psql provides variable substitution features similar to common Unix command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the psql meta-command \set. For example,

\set foo bar

sets the variable foo to the value bar. To retrieve the content of the variable, precede the name with a colon, for example:

\echo :foo

This works in both regular SQL commands and meta-commands; there is more detail in SQL Interpolation, below.

If you call \set without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command \unset. To show the values of all variables, call \set without any argument.

Note: The arguments of \set are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as \set :foo 'something' and get “soft links” or “variable variables” of Perl or PHP fame, respectively. Unfortunately (or fortunately?), there is no way to do anything useful with these constructs. On the other hand, \set bar :foo is a perfectly valid way to copy a variable.

A number of these variables are treated specially by psql. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of psql. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables’ names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

AUTOCOMMIT

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a BEGIN or START TRANSACTION SQL command. When off or unset, SQL commands are not committed until you explicitly issue COMMIT or END. The autocommit-off mode works by issuing an implicit BEGIN for you, just before any command that is not already in a transaction block and is not itself a BEGIN or other transaction-control command, nor a command that cannot be executed inside a transaction block (such as VACUUM).

Note: In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK. Also keep in mind that if you exit the session without committing, your work will be lost.
Note: The autocommit-on mode is PostgreSQL’s traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you might wish to set it in the system-wide psqlrc file or your ~/.psqlrc file.

COMP_KEYWORD_CASE

Determines which letter case to use when completing an SQL key word. If set to lower or upper, the completed word will be in lower or upper case, respectively. If set to preserve-lower or preserve-upper (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

ECHO

If set to all, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch -a. If set to queries, psql prints each query to standard output as it is sent to the server. The switch for this is -e. If set to errors, then only failed queries are displayed on standard error output. The switch for this is -b. If unset, or if set to none (or any other value than those above) then no queries are displayed.

ECHO_HIDDEN

When this variable is set to on and a backslash command queries the database, the query is first shown. This feature helps you to study PostgreSQL internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.) If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and executed.

ENCODING

The current client character set encoding.

FETCH_COUNT

If this variable is set to an integer value > 0, the results of SELECT queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query might fail after having already displayed some rows.

Tip: Although you can use any output format with this feature, the default aligned format tends to look bad because each group of FETCH_COUNT rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

HISTCONTROL

If this variable is set to ignorespace, lines which begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not
entered. A value of ignoreboth combines the two options. If unset, or if set to none (or any other value than those above), all lines read in interactive mode are saved on the history list.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTFILE**

The file name that will be used to store the history list. The default value is ~/.psql_history. For example, putting:

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in ~/.psqlrc will cause psql to maintain a separate history for each database.

**Note:** This feature was shamelessly plagiarized from Bash.

**HISTSIZE**

The number of commands to store in the command history. The default value is 500.

**Note:** This feature was shamelessly plagiarized from Bash.

**HOST**

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

**IGNOREEOF**

If unset, sending an EOF character (usually Control+D) to an interactive session of psql will terminate the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**Note:** This feature was shamelessly plagiarized from Bash.

**LASTOID**

The value of the last affected OID, as returned from an INSERT or \lo_import command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

**ON_ERROR_ROLLBACK**

When set to on, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to interactive, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to off, a statement in a transaction block that generates an error aborts the entire transaction. The error rollback mode works by issuing an implicit SAVEPOINT for you, just before each command that is in a transaction block, and then rolling back to the savepoint if the command fails.

**ON_ERROR_STOP**

By default, command processing continues after an error. When this variable is set to on, processing will instead stop immediately. In interactive mode, psql will return to the command prompt;
otherwise, psql will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have in invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

PORT
The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1
PROMPT2
PROMPT3
These specify what the prompts psql issues should look like. See Prompting below.

QUIET
Setting this variable to on is equivalent to the command line option -q. It is probably not too useful in interactive mode.

SHOW_CONTEXT
This variable can be set to the values never, errors, or always to control whether CONTEXT fields are displayed in messages from the server. The default is errors (meaning that context will be shown in error messages, but not in notice or warning messages). This setting has no effect when VERBOSITY is set to terse. (See also \errverbose, for use when you want a verbose version of the error you just got.)

SINGLELINE
Setting this variable to on is equivalent to the command line option -S.

SINGLESTEP
Setting this variable to on is equivalent to the command line option -s.

USER
The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

VERBOSITY
This variable can be set to the values default, verbose, or terse to control the verbosity of error reports. (See also \errverbose, for use when you want a verbose version of the error you just got.)

SQL Interpolation
A key feature of psql variables is that you can substitute (“interpolate”) them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, psql provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:). For example,

testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;

would query the table my_table. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.
When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :"foo";
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as ':foo' doesn’t work to produce a quoted literal from a variable’s value (and it would be unsafe if it did work, since it wouldn’t correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable’s value as a quoted string:

```
testdb=> \set content 'cat my_file.txt'
testdb=> INSERT INTO my_table VALUES (:'content');
```

(Note that this still won’t work if my_file.txt contains NUL bytes. psql does not support embedded NUL bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, :name, :’name’, or :"name") is not replaced unless the named variable is currently set. In any case, you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are PostgreSQL extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable’s value as an SQL literal or identifier is a psql extension.

**Prompting**

The prompts `psql` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `psql` requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

```
%M
```

The full host name (with domain name) of the database server, or `[local]` if the connection is over a Unix domain socket, or `[local:/dir/name]`, if the Unix domain socket is not at the compiled in default location.

```
%m
```

The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a Unix domain socket.
%>
The port number at which the database server is listening.
%n
The database session user name. (The expansion of this value might change during a database session as the result of the command \texttt{SET SESSION AUTHORIZATION}.)
%/
The name of the current database.
%~
Like %/, but the output is ~ (tilde) if the database is your default database.
%#
If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command \texttt{SET SESSION AUTHORIZATION}.)
%p
The process ID of the backend currently connected to.
%R
In prompt 1 normally =, but ^ if in single-line mode, or ! if the session is disconnected from the database (which can happen if \texttt{connect} fails). In prompt 2 %R is replaced by a character that depends on why \texttt{psql} expects more input: = if the command simply wasn’t terminated yet, but * if there is an unfinished /* ... */ comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or ( if there is an unmatched left parenthesis. In prompt 3 %R doesn’t produce anything.
%x
Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).
%l
The line number inside the current statement, starting from 1.
%\texttt{digits}
The character with the indicated octal code is substituted.
%@\texttt{name}:
The value of the \texttt{psql} variable \texttt{name}. See the section Variables for details.
%`\texttt{command}`
The output of \texttt{command}, similar to ordinary “back-tick” substitution.
%[ ... %]
Prompts can contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these can occur within the prompt. For example:
\texttt{testdb=> \set PROMPT1 ’%[\texttt{\%033[1;33;40m}}\%n@\texttt{\%033[0m}}%\texttt{%]’}
results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals.

To insert a percent sign into your prompt, write %%. The default prompts are ’%/%%’ for prompts 1 and 2, and ’>>’ for prompt 3.

**Note:** This feature was shamelessly plagiarized from tcsh.

**Command-Line Editing**

psql supports the Readline library for convenient line editing and retrieval. The command history is automatically saved when psql exits and is reloaded when psql starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```bash
$if psql
set disable-completion on
$endif
```

(This is not a psql but a Readline feature. Read its documentation for further details.)

**Environment**

**COLUMNS**

If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

**PAGER**

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. Use of the pager can be disabled by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

**PGDATABASE**

**PGHOST**

**PGPORT**

**PGUSER**

Default connection parameters (see Section 32.14).

**PSQL_EDITOR**

**EDITOR**

**VISUAL**

Editor used by the \e, \ef, and \ev commands. These variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.
When `\e`, `\ef`, or `\ev` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user’s editor. For editors such as Emacs or vi, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG=’+’
PSQL_EDITOR_LINENUMBER_ARG=’--line ’
```

The default is `+` on Unix systems (corresponding to the default editor vi, and useful for many other common editors); but there is no default on Windows systems.

**PSQL_HISTORY**

Alternative location for the command history file. Tilde (`~`) expansion is performed.

**PSQLRC**

Alternative location of the user’s `.psqlrc` file. Tilde (`~`) expansion is performed.

**SHELL**

Command executed by the `\!` command.

**TMPDIR**

Directory for storing temporary files. The default is `/tmp`.

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

**Files**

`.psqlrc` and `~/.psqlrc`

Unless it is passed an `-X` option, psql attempts to read and execute commands from the system-wide startup file (`psqlrc`) and then the user’s personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation’s “system configuration” directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `../etc/` relative to the directory containing the PostgreSQL executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user’s personal startup file is named `.psqlrc` and is sought in the invoking user’s home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user’s startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user’s personal startup file can be made psql-version-specific by appending a dash and the PostgreSQL major or minor release number to the file name, for example `~/.psqlrc-9.2` or `~/.psqlrc-9.2.5`. The most specific version-matching file will be read in preference to a non-version-specific file.

`.psql_history`

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.
The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

**Notes**

- `psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with servers of versions back to 7.4, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep around a copy of `psql` from each major version and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

- Before PostgreSQL 9.6, the `-c` option implied `-X(--no-psqlrc);` this is no longer the case.
- Before PostgreSQL 8.4, `psql` allowed the first argument of a single-letter backslash command to start directly after the command, without intervening whitespace. Now, some whitespace is required.

**Notes for Windows Users**

`psql` is built as a “console application”. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

- Set the code page by entering `cmd.exe /c chcp 1252`. (1252 is a code page that is appropriate for German; replace it with your value.) If you are using Cygwin, you can put this command in `/etc/profile`.
- Set the console font to `Lucida Console`, because the raster font does not work with the ANSI code page.

**Examples**

The first example shows how to spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (  
testdb{>}  first integer not null default 0,  
testdb{>}  second text)  
testdb=>  ;  
CREATE TABLE
```

Now look at the table definition again:
```sql
psql
testdb=> \d my_table
  Table "my_table"
  Attribute | Type       | Modifier
  -------------------------------
  first    | integer    | not null default 0
  second   | text       |

Now we change the prompt to something more interesting:

testdb=> \set PROMPT1 '%n@%m %~%R%# '
peter@localhost testdb=>

Let's assume you have filled the table with data and want to take a look at it:

peter@localhost testdb=> SELECT * FROM my_table;
  first | second
  -------+--------
     1 | one
     2 | two
     3 | three
     4 | four
(4 rows)

You can display tables in different ways by using the \pset command:

peter@localhost testdb=> \pset border 2
Border style is 2.
peter@localhost testdb=> SELECT * FROM my_table;
  | first | second |
  +-------+--------+
     1 | one |
     2 | two |
     3 | three |
     4 | four |
(4 rows)
peter@localhost testdb=> \pset border 0
Border style is 0.
peter@localhost testdb=> SELECT * FROM my_table;
  first | second
  ----- | ----- 
     1 | one
     2 | two
     3 | three
     4 | four
(4 rows)
peter@localhost testdb=> \pset border 1
Border style is 1.
peter@localhost testdb=> \pset format unaligned
Output format is unaligned.
peter@localhost testdb=> \pset fieldsep ","
Field separator is ",".
peter@localhost testdb=> \pset tuples_only
Showing only tuples.
peter@localhost testdb=> SELECT second, first FROM my_table;
```

1883
one, 1
two, 2
three, 3
four, 4

Alternatively, use the short commands:

code

```sql
peter@localhost testdb=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is on.
peter@localhost testdb=> SELECT * FROM my_table;
- [ RECORD 1 ] -
  first | 1
  second | one
- [ RECORD 2 ] -
  first | 2
  second | two
- [ RECORD 3 ] -
  first | 3
  second | three
- [ RECORD 4 ] -
  first | 4
  second | four
```

When suitable, query results can be shown in a crosstab representation with the \crosstabview command:

```
| first | second | gt2 |
|-------+--------+-----|
| 1 | one | f |
| 2 | two | f |
| 3 | three | t |
| 4 | four | t |
```

This second example shows a multiplication table with rows sorted in reverse numerical order and columns with an independent, ascending numerical order.

```
<table>
<thead>
<tr>
<th>A</th>
<th>101</th>
<th>102</th>
<th>103</th>
<th>104</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>404</td>
<td>408</td>
<td>412</td>
<td>416</td>
</tr>
</tbody>
</table>
```
reindexdb

Name
reindexdb — reindex a PostgreSQL database

Synopsis
reindexdb [connection-option...] [option...] [-s schema]... [-t table]... [-i index]... [dbname]

Description
reindexdb is a utility for rebuilding indexes in a PostgreSQL database.

reindexdb is a wrapper around the SQL command REINDEX. There is no effective difference between
reindexing databases via this utility and via other methods for accessing the server.

Options
reindexdb accepts the following command-line arguments:

-a
  --all
  Reindex all databases.

-d dbname
  [-d dbname=] dbname
  Specifies the name of the database to be reindexed. If this is not specified and -a (or --all) is
  not used, the database name is read from the environment variable PGDATABASE. If that is not
  set, the user name specified for the connection is used.

-e
  --echo
  Echo the commands that reindexdb generates and sends to the server.

-i index
  [-i index=] index
  Recreate index only. Multiple indexes can be recreated by writing multiple -i switches.

-q
  --quiet
  Do not display progress messages.
reindexdb

-s
--system

Reindex database’s system catalogs.

-S schema
--schema=schema

Reindex schema only. Multiple schemas can be reindexed by writing multiple -S switches.

-t table
--table=table

Reindex table only. Multiple tables can be reindexed by writing multiple -t switches.

-v
--verbose

Print detailed information during processing.

-V
--version

Print the reindexdb version and exit.

-?
--help

Show help about reindexdb command line arguments, and exit.

reindexdb also accepts the following command-line arguments for connection parameters:

-h host
--host=host

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

-p port
--port=port

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

-U username
--username=username

User name to connect as.

-w
--no-password

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
--password

Force reindexdb to prompt for a password before connecting to a database.

This option is never essential, since reindexdb will automatically prompt for a password if the server demands password authentication. However, reindexdb will waste a connection attempt
reindexdb

finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

--maintenance-db=dbname

Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the postgres database will be used, and if that does not exist, template1 will be used.

Environment

PGDATABASE
PGHOST
PGPORT
PGUSER

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

Diagnostics

In case of difficulty, see REINDEX and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes

reindexdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 32.15 for more information.

Examples

To reindex the database test:

$ reindexdb test

To reindex the table foo and the index bar in a database named abcd:

$ reindexdb --table foo --index bar abcd

See Also

REINDEX
vacuumdb

Name
vacuumdb — garbage-collect and analyze a PostgreSQL database

Synopsis
vacuumdb [connection-option...] [option...][ --table |-t table [( column [...])]] ...[dbname]

vacuumdb [connection-option...][option...] --all | -a

Description
vacuumdb is a utility for cleaning a PostgreSQL database. vacuumdb will also generate internal statistics used by the PostgreSQL query optimizer.

vacuumdb is a wrapper around the SQL command VACUUM. There is no effective difference between vacuuming and analyzing databases via this utility and via other methods for accessing the server.

Options
vacuumdb accepts the following command-line arguments:

- a
--all
Vacuum all databases.

[-d] dbname
[--dbname=] dbname

Specifies the name of the database to be cleaned or analyzed. If this is not specified and -a (or --all) is not used, the database name is read from the environment variable PGDATABASE. If that is not set, the user name specified for the connection is used.

- e
--echo
Echo the commands that vacuumdb generates and sends to the server.

- f
--full
Perform “full” vacuuming.

- F
--freeze
Aggressively “freeze” tuples.
Execute the vacuum or analyze commands in parallel by running `njobs` commands simultaneously. This option reduces the time of the processing but it also increases the load on the database server.

`vacuumdb` will open `njobs` connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Note that using this mode together with the `-f (FULL)` option might cause deadlock failures if certain system catalogs are processed in parallel.

Do not display progress messages.

Clean or analyze `table` only. Column names can be specified only in conjunction with the `--analyze` or `--analyze-only` options. Multiple tables can be vacuumed by writing multiple `-t` switches.

**Tip:** If you specify columns, you probably have to escape the parentheses from the shell. (See examples below.)

Print detailed information during processing.

Print the `vacuumdb` version and exit.

Also calculate statistics for use by the optimizer.

Only calculate statistics for use by the optimizer (no vacuum).

Only calculate statistics for use by the optimizer (no vacuum), like `--analyze-only`. Run several (currently three) stages of analyze with different configuration settings, to produce usable statistics faster.

This option is useful to analyze a database that was newly populated from a restored dump or by `pg_upgrade`. This option will try to create some statistics as fast as possible, to make the database usable, and then produce full statistics in the subsequent stages.

Show help about `vacuumdb` command line arguments, and exit.
vacuumdb also accepts the following command-line arguments for connection parameters:

- **-h host**
  --host=host

  Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

- **-p port**
  --port=port

  Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

- **-U username**
  --username=USERNAME

  User name to connect as.

- **-w**
  --no-password

  Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

- **-W**
  --password

  Force vacuumdb to prompt for a password before connecting to a database.

  This option is never essential, since vacuumdb will automatically prompt for a password if the server demands password authentication. However, vacuumdb will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

- **--maintenance-db=dbname**

  Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the postgres database will be used, and if that does not exist, template1 will be used.

### Environment

**PGDATABASE**
**PGHOST**
**PGPORT**
**PGUSER**

Default connection parameters

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).
Diagnostics
In case of difficulty, see VACUUM and psql for discussions of potential problems and error messages. The database server must be running at the targeted host. Also, any default connection settings and environment variables used by the libpq front-end library will apply.

Notes
vacuumdb might need to connect several times to the PostgreSQL server, asking for a password each time. It is convenient to have a ~/.pgpass file in such cases. See Section 32.15 for more information.

Examples
To clean the database test:

$ vacuumdb test

To clean and analyze for the optimizer a database named bigdb:

$ vacuumdb --analyze bigdb

To clean a single table foo in a database named xyzzy, and analyze a single column bar of the table for the optimizer:

$ vacuumdb --analyze --verbose --table 'foo(bar)' xyzzy

VACUUM
III. PostgreSQL Server Applications

This part contains reference information for PostgreSQL server applications and support utilities. These commands can only be run usefully on the host where the database server resides. Other utility programs are listed in Reference II, *PostgreSQL Client Applications*. 
initdb

Name

initdb — create a new PostgreSQL database cluster

Synopsis

initdb [option...] [-p qdata |-D] directory

Description

initdb creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance.

Creating a database cluster consists of creating the directories in which the database data will live, generating the shared catalog tables (tables that belong to the whole cluster rather than to any particular database), and creating the template1 and postgres databases. When you later create a new database, everything in the template1 database is copied. (Therefore, anything installed in template1 is automatically copied into each database created later.) The postgres database is a default database meant for use by users, utilities and third party applications.

Although initdb will attempt to create the specified data directory, it might not have permission if the parent directory of the desired data directory is root-owned. To initialize in such a setup, create an empty data directory as root, then use chown to assign ownership of that directory to the database user account, then su to become the database user to run initdb.

initdb must be run as the user that will own the server process, because the server needs to have access to the files and directories that initdb creates. Since the server cannot be run as root, you must not run initdb as root either. (It will in fact refuse to do so.)

initdb initializes the database cluster’s default locale and character set encoding. The character set encoding, collation order (LC_COLLATE) and character set classes (LC_CTYPE, e.g. upper, lower, digit) can be set separately for a database when it is created. initdb determines those settings for the template1 database, which will serve as the default for all other databases.

To alter the default collation order or character set classes, use the --lc-collate and --lc-ctype options. Collation orders other than C or POSIX also have a performance penalty. For these reasons it is important to choose the right locale when running initdb.

The remaining locale categories can be changed later when the server is started. You can also use --locale to set the default for all locale categories, including collation order and character set classes. All server locale values (lc_*) can be displayed via SHOW ALL. More details can be found in Section 23.1.

To alter the default encoding, use the --encoding. More details can be found in Section 23.3.
Options

-A authmethod
--auth=authmethod

This option specifies the authentication method for local users used in pg_hba.conf (host and local lines). Do not use trust unless you trust all local users on your system. trust is the default for ease of installation.

--auth-host=authmethod

This option specifies the authentication method for local users via TCP/IP connections used in pg_hba.conf (host lines).

--auth-local=authmethod

This option specifies the authentication method for local users via Unix-domain socket connections used in pg_hba.conf (local lines).

-D directory
--pgdata=directory

This option specifies the directory where the database cluster should be stored. This is the only information required by initdb, but you can avoid writing it by setting the PGDATA environment variable, which can be convenient since the database server (postgres) can find the database directory later by the same variable.

-E encoding
--encoding=encoding

Selects the encoding of the template database. This will also be the default encoding of any database you create later, unless you override it there. The default is derived from the locale, or SQL_ASCII if that does not work. The character sets supported by the PostgreSQL server are described in Section 23.3.1.

-k
--data-checksums

Use checksums on data pages to help detect corruption by the I/O system that would otherwise be silent. Enabling checksums may incur a noticeable performance penalty. This option can only be set during initialization, and cannot be changed later. If set, checksums are calculated for all objects, in all databases.

--locale=locale

Sets the default locale for the database cluster. If this option is not specified, the locale is inherited from the environment that initdb runs in. Locale support is described in Section 23.1.

--lc-collate=locale
--lc-type=locale
--lc-messages=locale
--lc-monetary=locale
--lc-numeric=locale
--lc-time=locale

Like --locale, but only sets the locale in the specified category.

--no-local

Equivalent to --locale=C.
-N
--nosync
By default, initdb will wait for all files to be written safely to disk. This option causes initdb to return without waiting, which is faster, but means that a subsequent operating system crash can leave the data directory corrupt. Generally, this option is useful for testing, but should not be used when creating a production installation.

--pwfile=filename
Makes initdb read the database superuser’s password from a file. The first line of the file is taken as the password.

-S
--sync-only
Safely write all database files to disk and exit. This does not perform any of the normal initdb operations.

-T CFG
--text-search-config=CFG
Sets the default text search configuration. See default_text_search_config for further information.

-U username
--username=username
Selects the user name of the database superuser. This defaults to the name of the effective user running initdb. It is really not important what the superuser’s name is, but one might choose to keep the customary name postgres, even if the operating system user’s name is different.

-W
--pwprompt
Makes initdb prompt for a password to give the database superuser. If you don’t plan on using password authentication, this is not important. Otherwise you won’t be able to use password authentication until you have a password set up.

-X directory
--xlogdir=directory
This option specifies the directory where the transaction log should be stored.

Other, less commonly used, options are also available:

-d
--debug
Print debugging output from the bootstrap backend and a few other messages of lesser interest for the general public. The bootstrap backend is the program initdb uses to create the catalog tables. This option generates a tremendous amount of extremely boring output.

-L directory
Specifies where initdb should find its input files to initialize the database cluster. This is normally not necessary. You will be told if you need to specify their location explicitly.
initdb

-\n
--noclean

By default, when initdb determines that an error prevented it from completely creating the database cluster, it removes any files it might have created before discovering that it cannot finish the job. This option inhibits tidying-up and is thus useful for debugging.

Other options:

- V
  --version

  Print the initdb version and exit.

- ?
  --help

  Show help about initdb command line arguments, and exit.

Environment

PGDATA

  Specifies the directory where the database cluster is to be stored; can be overridden using the --D option.

TZ

  Specifies the default time zone of the created database cluster. The value should be a full time zone name (see Section 8.5.3).

This utility, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14).

Notes

initdb can also be invoked via pg_ctl initdb.

pg_ctl, postgres
**pg_archivecleanup**

**Name**

`pg_archivecleanup` — clean up PostgreSQL WAL archive files

**Synopsis**

`pg_archivecleanup [option...] archivelocation oldestkeptwalfile`

**Description**

`pg_archivecleanup` is designed to be used as an `archive_cleanup_command` to clean up WAL file archives when running as a standby server (see Section 26.2). `pg_archivecleanup` can also be used as a standalone program to clean WAL file archives.

To configure a standby server to use `pg_archivecleanup`, put this into its `recovery.conf` configuration file:

```
archive_cleanup_command = 'pg_archivecleanup archivelocation \%r'
```

where `archivelocation` is the directory from which WAL segment files should be removed.

When used within `archive_cleanup_command`, all WAL files logically preceding the value of the `%r` argument will be removed from `archivelocation`. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the `archivelocation` is a transient staging area for this particular standby server, but not when the `archivelocation` is intended as a long-term WAL archive area, or when multiple standby servers are recovering from the same archive location.

When used as a standalone program all WAL files logically preceding the `oldestkeptwalfile` will be removed from `archivelocation`. In this mode, if you specify a `.partial` or `.backup` file name, then only the file prefix will be used as the `oldestkeptwalfile`. This treatment of `.backup` file name allows you to remove all WAL files archived prior to a specific base backup without error. For example, the following example will remove all files older than WAL file name `000000010000003700000010`:

```
pg_archivecleanup -d archive 00000001000000370000000010.00000020.backup
```

`pg_archivecleanup` assumes that `archivelocation` is a directory readable and writable by the server-owning user.
Options

`pg_archivecleanup` accepts the following command-line arguments:

- `-d`
  Print lots of debug logging output on stderr.

- `-n`
  Print the names of the files that would have been removed on stdout (performs a dry run).

- `-V`
  --version
  Print the `pg_archivecleanup` version and exit.

- `-x extension`
  Provide an extension that will be stripped from all file names before deciding if they should be deleted. This is typically useful for cleaning up archives that have been compressed during storage, and therefore have had an extension added by the compression program. For example:
  
  - `x .gz`

- `--help`
  Show help about `pg_archivecleanup` command line arguments, and exit.

Notes

`pg_archivecleanup` is designed to work with PostgreSQL 8.0 and later when used as a standalone utility, or with PostgreSQL 9.0 and later when used as an archive cleanup command.

`pg_archivecleanup` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```
archive_cleanup_command = 'pg_archivecleanup -d /mnt/standby/archive %r 2>>cleanup.log'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby. This will:

- produce debugging output in `cleanup.log`
- remove no-longer-needed files from the archive directory

`pg_standby`
Name

pg_controldata — display control information of a PostgreSQL database cluster

Synopsis

pg_controldata [option] [[-D] datadir]

Description

pg_controldata prints information initialized during initdb, such as the catalog version. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide, and not specific to any one database.

This utility can only be run by the user who initialized the cluster because it requires read access to the data directory. You can specify the data directory on the command line, or use the environment variable PGDATA. This utility supports the options -V and --version, which print the pg_controldata version and exit. It also supports options -? and --help, which output the supported arguments.

Environment

PGDATA

    Default data directory location
**pg_ctl**

**Name**

pg_ctl — initialize, start, stop, or control a PostgreSQL server

**Synopsis**

pg_ctl init[db] [-s] [-D datadir] [-o initdb-options]

pg_ctl stop [-W] [-t seconds] [-s] [-D datadir] [-m smart | fast | immediate] [-o options]

pg_ctl restart [-w] [-t seconds] [-s] [-D datadir] [-c] [-m smart | fast | immediate] [-o options]

pg_ctl reload [-s] [-D datadir]

pg_ctl status [-D datadir]

pg_ctl promote [-s] [-D datadir]

pg_ctl kill signal_name process_id

pg_ctl unregister [-N servicename]

**Description**

pg_ctl is a utility for initializing a PostgreSQL database cluster, starting, stopping, or restarting the PostgreSQL database server (postgres), or displaying the status of a running server. Although the server can be started manually, pg_ctl encapsulates tasks such as redirecting log output and properly detaching from the terminal and process group. It also provides convenient options for controlled shutdown.

The init or initdb mode creates a new PostgreSQL database cluster. A database cluster is a collection of databases that are managed by a single server instance. This mode invokes the initdb command. See initdb for details.

In start mode, a new server is launched. The server is started in the background, and its standard input is attached to /dev/null (or nul on Windows). On Unix-like systems, by default, the server’s
standard output and standard error are sent to pg_ctl’s standard output (not standard error). The standard output of pg_ctl should then be redirected to a file or piped to another process such as a log rotating program like rotatelogs; otherwise postgres will write its output to the controlling terminal (from the background) and will not leave the shell’s process group. On Windows, by default the server’s standard output and standard error are sent to the terminal. These default behaviors can be changed by using -l to append the server’s output to a log file. Use of either -l or output redirection is recommended.

In stop mode, the server that is running in the specified data directory is shut down. Three different shutdown methods can be selected with the -m option. “Smart” mode waits for all active clients to disconnect and any online backup to finish. If the server is in hot standby, recovery and streaming replication will be terminated once all clients have disconnected. “Fast” mode (the default) does not wait for clients to disconnect and will terminate an online backup in progress. All active transactions are rolled back and clients are forcibly disconnected, then the server is shut down. “Immediate” mode will abort all server processes immediately, without a clean shutdown. This will lead to a crash-recovery run on the next restart.

restart mode effectively executes a stop followed by a start. This allows changing the postgres command-line options. restart might fail if relative paths specified were specified on the command-line during server start.

reload mode simply sends the postgres process a SIGHUP signal, causing it to reread its configuration files (postgresql.conf, pg_hba.conf, etc.). This allows changing of configuration-file options that do not require a complete restart to take effect.

status mode checks whether a server is running in the specified data directory. If it is, the PID and the command line options that were used to invoke it are displayed. If the server is not running, the process returns an exit status of 3. If an accessible data directory is not specified, the process returns an exit status of 4.

In promote mode, the standby server that is running in the specified data directory is commanded to exit recovery and begin read-write operations.

kill mode allows you to send a signal to a specified process. This is particularly valuable for Microsoft Windows which does not have a kill command. Use --help to see a list of supported signal names.

register mode allows you to register a system service on Microsoft Windows. The -S option allows selection of service start type, either “auto” (start service automatically on system startup) or “demand” (start service on demand).

unregister mode allows you to unregister a system service on Microsoft Windows. This undoes the effects of the register command.

Options

-c
--core-file

Attempt to allow server crashes to produce core files, on platforms where this is possible, by lifting any soft resource limit placed on core files. This is useful in debugging or diagnosing problems by allowing a stack trace to be obtained from a failed server process.
Specifies the file system location of the database configuration files. If this is omitted, the environment variable PGDATA is used.

Appends the server log output to filename. If the file does not exist, it is created. The umask is set to 077, so access to the log file is disallowed to other users by default.

Specifies the shutdown mode. mode can be smart, fast, or immediate, or the first letter of one of these three. If this is omitted, fast is used.

Specifies options to be passed directly to the postgres command; multiple option invocations are appended.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

Specifies options to be passed directly to the initdb command.

The options should usually be surrounded by single or double quotes to ensure that they are passed through as a group.

Specifies the location of the postgres executable. By default the postgres executable is taken from the same directory as pg_ctl, or failing that, the hard-wired installation directory. It is not necessary to use this option unless you are doing something unusual and get errors that the postgres executable was not found.

In init mode, this option analogously specifies the location of the initdb executable.

Print only errors, no informational messages.

The maximum number of seconds to wait when waiting for startup or shutdown to complete. Defaults to the value of the PGCTLTIMEOUT environment variable or, if not set, to 60 seconds.

Print the pg_ctl version and exit.

Wait for the startup or shutdown to complete. Waiting is the default option for shutdowns, but not startups. When waiting for startup, pg_ctl repeatedly attempts to connect to the server. When waiting for shutdown, pg_ctl waits for the server to remove its PID file. This option allows the entry of an SSL passphrase on startup. pg_ctl returns an exit code based on the success of the startup or shutdown.
pg_ctl

-W
Do not wait for startup or shutdown to complete. This is the default for start and restart modes.

-?
--help
Show help about pg_ctl command line arguments, and exit.

Options for Windows

-e source
Name of the event source for pg_ctl to use for logging to the event log when running as a Windows service. The default is PostgreSQL. Note that this only controls the logging from pg_ctl itself; once started, the server will use the event source specified by event_source. Should the server fail during early startup, it might also log using the default event source PostgreSQL.

-N servicename
Name of the system service to register. The name will be used as both the service name and the display name.

-P password
Password for the user to start the service.

-S start-type
Start type of the system service to register. start-type can be auto, or demand, or the first letter of one of these two. If this is omitted, auto is used.

-U username
User name for the user to start the service. For domain users, use the format DOMAIN\username.

Environment

PGCTLT_TIMEOUT
Default limit on the number of seconds to wait when waiting for startup or shutdown to complete. If not set, the default is 60 seconds.

PGDATA
Default data directory location.

pg_ctl, like most other PostgreSQL utilities, also uses the environment variables supported by libpq (see Section 32.14). For additional server variables, see postgres.

Files

postmaster.pid
The existence of this file in the data directory is used to help pg_ctl determine if the server is currently running.
If this file exists in the data directory, pg_ctl (in restart mode) will pass the contents of the file as options to postgres, unless overridden by the -o option. The contents of this file are also displayed in status mode.

Examples

Starting the Server

To start the server:

$ pg_ctl start

To start the server, waiting until the server is accepting connections:

$ pg_ctl -w start

To start the server using port 5433, and running without fsync, use:

$ pg_ctl -o "-F -p 5433" start

Stopping the Server

To stop the server, use:

$ pg_ctl stop

The -m option allows control over how the server shuts down:

$ pg_ctl stop -m fast

Restarting the Server

Restarting the server is almost equivalent to stopping the server and starting it again, except that pg_ctl saves and reuses the command line options that were passed to the previously running instance. To restart the server in the simplest form, use:

$ pg_ctl restart

To restart the server, waiting for it to shut down and restart:

$ pg_ctl -w restart
To restart using port 5433, disabling fsync upon restart:

$ pg_ctl -o "-F -p 5433" restart

Showing the Server Status

Here is sample status output from pg_ctl:

$ pg_ctl status
pg_ctl: server is running (PID: 13718)
/usr/local/pgsql/bin/postgres "-D" "/usr/local/pgsql/data" "-p" "5433" "-B" "128"

This is the command line that would be invoked in restart mode.

**pg_resetxlog**

**Name**

`pg_resetxlog` — reset the write-ahead log and other control information of a PostgreSQL database cluster

**Synopsis**

```
pg_resetxlog [-f] [-n] [option...] [-D datadir]
```

**Description**

`pg_resetxlog` clears the write-ahead log (WAL) and optionally resets some other control information stored in the `pg_control` file. This function is sometimes needed if these files have become corrupted. It should be used only as a last resort, when the server will not start due to such corruption.

After running this command, it should be possible to start the server, but bear in mind that the database might contain inconsistent data due to partially-committed transactions. You should immediately dump your data, run `initdb`, and reload. After reload, check for inconsistencies and repair as needed.

This utility can only be run by the user who installed the server, because it requires read/write access to the data directory. For safety reasons, you must specify the data directory on the command line. `pg_resetxlog` does not use the environment variable `PGDATA`.

If `pg_resetxlog` complains that it cannot determine valid data for `pg_control`, you can force it to proceed anyway by specifying the `-f` (force) option. In this case plausible values will be substituted for the missing data. Most of the fields can be expected to match, but manual assistance might be needed for the next OID, next transaction ID and epoch, next multitransaction ID and offset, and WAL starting address fields. These fields can be set using the options discussed below. If you are not able to determine correct values for all these fields, `-f` can still be used, but the recovered database must be treated with even more suspicion than usual: an immediate dump and reload is imperative. *Do not* execute any data-modifying operations in the database before you dump, as any such action is likely to make the corruption worse.

**Options**

- **-f**

  Force `pg_resetxlog` to proceed even if it cannot determine valid data for `pg_control`, as explained above.

- **-n**

  The `-n` (no operation) option instructs `pg_resetxlog` to print the values reconstructed from `pg_control` and values about to be changed, and then exit without modifying anything. This is mainly a debugging tool, but can be useful as a sanity check before allowing `pg_resetxlog` to proceed for real.
The following options are only needed when `pg_resetxlog` is unable to determine appropriate values by reading `pg_control`. Safe values can be determined as described below. For values that take numeric arguments, hexadecimal values can be specified by using the prefix 0x.

- **-c xid,xid**
  Manually set the oldest and newest transaction IDs for which the commit time can be retrieved.

  A safe value for the oldest transaction ID for which the commit time can be retrieved (first part) can be determined by looking for the numerically smallest file name in the directory `pg_commit_ts` under the data directory. Conversely, a safe value for the newest transaction ID for which the commit time can be retrieved (second part) can be determined by looking for the numerically greatest file name in the same directory. The file names are in hexadecimal.

- **-e xid_epoch**
  Manually set the next transaction ID’s epoch.

  The transaction ID epoch is not actually stored anywhere in the database except in the field that is set by `pg_resetxlog`, so any value will work so far as the database itself is concerned. You might need to adjust this value to ensure that replication systems such as Slony-I and Skytools work correctly — if so, an appropriate value should be obtainable from the state of the downstream replicated database.

- **-l xlogfile**
  Manually set the WAL starting address.

  The WAL starting address should be larger than any WAL segment file name currently existing in the directory `pg_xlog` under the data directory. These names are also in hexadecimal and have three parts. The first part is the “timeline ID” and should usually be kept the same. For example, if `00000001000000320000004A` is the largest entry in `pg_xlog`, use `-l 00000001000000320000004B` or higher.

  **Note:** `pg_resetxlog` itself looks at the files in `pg_xlog` and chooses a default `-l` setting beyond the last existing file name. Therefore, manual adjustment of `-l` should only be needed if you are aware of WAL segment files that are not currently present in `pg_xlog`, such as entries in an offline archive; or if the contents of `pg_xlog` have been lost entirely.

- **-m mxid,mxid**
  Manually set the next and oldest multitransaction ID.

  A safe value for the next multitransaction ID (first part) can be determined by looking for the numerically largest file name in the directory `pg_multixact/offsets` under the data directory, adding one, and then multiplying by 65536 (0x10000). Conversely, a safe value for the oldest multitransaction ID (second part of `-m`) can be determined by looking for the numerically smallest file name in the same directory and multiplying by 65536. The file names are in hexadecimal, so the easiest way to do this is to specify the option value in hexadecimal and append four zeroes.
-o oid

Manually set the next OID.

There is no comparably easy way to determine a next OID that’s beyond the largest one in the database, but fortunately it is not critical to get the next-OID setting right.

-O mxoff

Manually set the next multitransaction offset.

A safe value can be determined by looking for the numerically largest file name in the directory pg_multixact/members under the data directory, adding one, and then multiplying by 52352 (0xCC80). The file names are in hexadecimal. There is no simple recipe such as the ones for other options of appending zeroes.

-x xid

Manually set the next transaction ID.

A safe value can be determined by looking for the numerically largest file name in the directory pg_clog under the data directory, adding one, and then multiplying by 1048576 (0x100000). Note that the file names are in hexadecimal. It is usually easiest to specify the option value in hexadecimal too. For example, if 0011 is the largest entry in pg_clog, -x 0x1200000 will work (five trailing zeroes provide the proper multiplier).

Notes

This command must not be used when the server is running. pg_resetxlog will refuse to start up if it finds a server lock file in the data directory. If the server crashed then a lock file might have been left behind; in that case you can remove the lock file to allow pg_resetxlog to run. But before you do so, make doubly certain that there is no server process still alive.

pg_resetxlog works only with servers of the same major version.

pg_controldata
**pg_rewind**

**Name**

`pg_rewind` — synchronize a PostgreSQL data directory with another data directory that was forked from it

**Synopsis**

```
pg_rewind [option...] [-D | --target-pgdata] directory (--source-pgdata=directory | --source-server=connstr)
```

**Description**

`pg_rewind` is a tool for synchronizing a PostgreSQL cluster with another copy of the same cluster, after the clusters’ timelines have diverged. A typical scenario is to bring an old master server back online after failover as a standby that follows the new master.

The result is equivalent to replacing the target data directory with the source one. Only changed blocks from relation files are copied; all other files are copied in full, including configuration files. The advantage of `pg_rewind` over taking a new base backup, or tools like rsync, is that `pg_rewind` does not require reading through unchanged blocks in the cluster. This makes it a lot faster when the database is large and only a small fraction of blocks differ between the clusters.

`pg_rewind` examines the timeline histories of the source and target clusters to determine the point where they diverged, and expects to find WAL in the target cluster’s `pg_xlog` directory reaching all the way back to the point of divergence. The point of divergence can be found either on the target timeline, the source timeline, or their common ancestor. In the typical failover scenario where the target cluster was shut down soon after the divergence, this is not a problem, but if the target cluster ran for a long time after the divergence, the old WAL files might no longer be present. In that case, they can be manually copied from the WAL archive to the `pg_xlog` directory, or fetched on startup by configuring `recovery.conf`. The use of `pg_rewind` is not limited to failover, e.g. a standby server can be promoted, run some write transactions, and then rewinded to become a standby again.

When the target server is started for the first time after running `pg_rewind`, it will go into recovery mode and replay all WAL generated in the source server after the point of divergence. If some of the WAL was no longer available in the source server when `pg_rewind` was run, and therefore could not be copied by the `pg_rewind` session, it must be made available when the target server is started. This can be done by creating a `recovery.conf` file in the target data directory with a suitable `restore_command`.

`pg_rewind` requires that the target server either has the `wal_log_hints` option enabled in `postgresql.conf` or data checksums enabled when the cluster was initialized with `initdb`. Neither of these are currently on by default. `full_page_writes` must also be set to `on`, but is enabled by default.
Warning

If pg_rewind fails while processing, then the data folder of the target is likely not in a state that can be recovered. In such a case, taking a new fresh backup is recommended.

pg_rewind will fail immediately if it finds files it cannot write directly to. This can happen for example when the source and the target server use the same file mapping for read-only SSL keys and certificates. If such files are present on the target server it is recommended to remove them before running pg_rewind. After doing the rewind, some of those files may have been copied from the source, in which case it may be necessary to remove the data copied and restore back the set of links used before the rewind.

Options

pg_rewind accepts the following command-line arguments:

-D directory
--target-pgdata=directory

This option specifies the target data directory that is synchronized with the source. The target server must be shut down cleanly before running pg_rewind.

--source-pgdata=directory

Specifies the filesystem path to the data directory of the source server to synchronize the target with. This option requires the source server to be cleanly shut down.

--source-server=connstr

Specifies a libpq connection string to connect to the source PostgreSQL server to synchronize the target with. The connection must be a normal (non-replication) connection with superuser access. This option requires the source server to be running and not in recovery mode.

-n
--dry-run

Do everything except actually modifying the target directory.

-P
--progress

Enables progress reporting. Turning this on will deliver an approximate progress report while copying data from the source cluster.

--debug

Print verbose debugging output that is mostly useful for developers debugging pg_rewind.

-V
--version

Display version information, then exit.

-?
--help

Show help, then exit.
Environment

When `--source-server` option is used, `pg_rewind` also uses the environment variables supported by libpq (see Section 32.14).

Notes

When executing `pg_rewind` using an online cluster as source which has been recently promoted, it is necessary to execute a `CHECKPOINT` after promotion so as its control file reflects up-to-date timeline information, which is used by `pg_rewind` to check if the target cluster can be rewound using the designated source cluster.

How it works

The basic idea is to copy all file system-level changes from the source cluster to the target cluster:

1. Scan the WAL log of the target cluster, starting from the last checkpoint before the point where the source cluster’s timeline history forked off from the target cluster. For each WAL record, record each data block that was touched. This yields a list of all the data blocks that were changed in the target cluster, after the source cluster forked off.

2. Copy all those changed blocks from the source cluster to the target cluster, either using direct file system access (`--source-pgdata`) or SQL (`--source-server`).

3. Copy all other files such as `pg_clog` and configuration files from the source cluster to the target cluster (everything except the relation files).

4. Apply the WAL from the source cluster, starting from the checkpoint created at failover. (Strictly speaking, `pg_rewind` doesn’t apply the WAL, it just creates a backup label file that makes PostgreSQL start by replaying all WAL from that checkpoint forward.)
**pg_test_fsync**

**Name**

pg_test_fsync — determine fastest `wal_sync_method` for PostgreSQL

**Synopsis**

`pg_test_fsync [option...]`

**Description**

`pg_test_fsync` is intended to give you a reasonable idea of what the fastest `wal_sync_method` is on your specific system, as well as supplying diagnostic information in the event of an identified I/O problem. However, differences shown by `pg_test_fsync` might not make any significant difference in real database throughput, especially since many database servers are not speed-limited by their transaction logs. `pg_test_fsync` reports average file sync operation time in microseconds for each `wal_sync_method`, which can also be used to inform efforts to optimize the value of `commit_delay`.

**Options**

`pg_test_fsync` accepts the following command-line options:

- `-f`
  --filename
  Specifies the file name to write test data in. This file should be in the same file system that the `pg_xlog` directory is or will be placed in. (`pg_xlog` contains the WAL files.) The default is `pg_test_fsync.out` in the current directory.

- `-s`
  --secs-per-test
  Specifies the number of seconds for each test. The more time per test, the greater the test’s accuracy, but the longer it takes to run. The default is 5 seconds, which allows the program to complete in under 2 minutes.

- `-V`
  --version
  Print the `pg_test_fsync` version and exit.

- `?-`
  --help
  Show help about `pg_test_fsync` command line arguments, and exit.
See Also

postgres
pg_test_timing

Name

pg_test_timing — measure timing overhead

Synopsis

pg_test_timing [option...]

Description

pg_test_timing is a tool to measure the timing overhead on your system and confirm that the system
time never moves backwards. Systems that are slow to collect timing data can give less accurate
EXPLAIN ANALYZE results.

Options

pg_test_timing accepts the following command-line options:

-d duration
--duration=duration

Specifies the test duration, in seconds. Longer durations give slightly better accuracy, and are
more likely to discover problems with the system clock moving backwards. The default test
duration is 3 seconds.

-V
--version

Print the pg_test_timing version and exit.

-?
--help

Show help about pg_test_timing command line arguments, and exit.

Usage

Interpreting results

Good results will show most (>90%) individual timing calls take less than one microsecond. Average
per loop overhead will be even lower, below 100 nanoseconds. This example from an Intel i7-860
system using a TSC clock source shows excellent performance:

Testing timing overhead for 3 seconds.
Per loop time including overhead: 35.96 nsec
Histogram of timing durations:
Note that different units are used for the per loop time than the histogram. The loop can have resolution within a few nanoseconds (nsec), while the individual timing calls can only resolve down to one microsecond (usec).

**Measuring executor timing overhead**

When the query executor is running a statement using `EXPLAIN ANALYZE`, individual operations are timed as well as showing a summary. The overhead of your system can be checked by counting rows with the `psql` program:

```sql
CREATE TABLE t AS SELECT * FROM generate_series(1,100000);
\timing
SELECT COUNT(*) FROM t;
EXPLAIN ANALYZE SELECT COUNT(*) FROM t;
```

The i7-860 system measured runs the count query in 9.8 ms while the `EXPLAIN ANALYZE` version takes 16.6 ms, each processing just over 100,000 rows. That 6.8 ms difference means the timing overhead per row is 68 ns, about twice what `pg_test_timing` estimated it would be. Even that relatively small amount of overhead is making the fully timed count statement take almost 70% longer. On more substantial queries, the timing overhead would be less problematic.

**Changing time sources**

On some newer Linux systems, it’s possible to change the clock source used to collect timing data at any time. A second example shows the slowdown possible from switching to the slower `acpi_pm` time source, on the same system used for the fast results above:

```bash
# cat /sys/devices/system/clocksource/clocksource0/available_clocksource
  tsc hpet acpi_pm
# echo acpi_pm > /sys/devices/system/clocksource/clocksource0/current_clocksource
# pg_test_timing
Per loop time including overhead: 722.92 nsec
Histogram of timing durations:
< usec  % of total  count
  1  27.84870  1155682
  2  72.05956  2990371
  4  0.07810   3241
  8  0.01357   563
 16  0.00007   3
```

In this configuration, the sample `EXPLAIN ANALYZE` above takes 115.9 ms. That’s 1061 nsec of timing overhead, again a small multiple of what’s measured directly by this utility. That much timing
overhead means the actual query itself is only taking a tiny fraction of the accounted for time, most of it is being consumed in overhead instead. In this configuration, any `EXPLAIN ANALYZE` totals involving many timed operations would be inflated significantly by timing overhead.

FreeBSD also allows changing the time source on the fly, and it logs information about the timer selected during boot:

```
# dmesg | grep "Timecounter"
Timecounter "ACPI-fast" frequency 3579545 Hz quality 900
Timecounter "i8254" frequency 1193182 Hz quality 0
Timecounters tick every 10.000 msec
Timecounter "TSC" frequency 2531787134 Hz quality 800
# sysctl kern.timecounter.hardware=TSC
kern.timecounter.hardware: ACPI-fast -> TSC
```

Other systems may only allow setting the time source on boot. On older Linux systems the "clock" kernel setting is the only way to make this sort of change. And even on some more recent ones, the only option you’ll see for a clock source is "jiffies". Jiffies are the older Linux software clock implementation, which can have good resolution when it’s backed by fast enough timing hardware, as in this example:

```
$ cat /sys/devices/system/clocksource/clocksource0/available_clocksource
jiffies
$ dmesg | grep time.c
time.c: Using 3.579545 MHz WALL PM GTOD PIT/TSC timer.
time.c: Detected 2400.153 MHz processor.
$ pg_test_timing
Testing timing overhead for 3 seconds.
Per timing duration including loop overhead: 97.75 ns
```

### Clock hardware and timing accuracy

Collecting accurate timing information is normally done on computers using hardware clocks with various levels of accuracy. With some hardware the operating systems can pass the system clock time almost directly to programs. A system clock can also be derived from a chip that simply provides timing interrupts, periodic ticks at some known time interval. In either case, operating system kernels provide a clock source that hides these details. But the accuracy of that clock source and how quickly it can return results varies based on the underlying hardware.

Inaccurate time keeping can result in system instability. Test any change to the clock source very carefully. Operating system defaults are sometimes made to favor reliability over best accuracy. And if you are using a virtual machine, look into the recommended time sources compatible with it. Virtual hardware faces additional difficulties when emulating timers, and there are often per operating system settings suggested by vendors.
The Time Stamp Counter (TSC) clock source is the most accurate one available on current generation CPUs. It’s the preferred way to track the system time when it’s supported by the operating system and the TSC clock is reliable. There are several ways that TSC can fail to provide an accurate timing source, making it unreliable. Older systems can have a TSC clock that varies based on the CPU temperature, making it unusable for timing. Trying to use TSC on some older multicore CPUs can give a reported time that’s inconsistent among multiple cores. This can result in the time going backwards, a problem this program checks for. And even the newest systems can fail to provide accurate TSC timing with very aggressive power saving configurations.

Newer operating systems may check for the known TSC problems and switch to a slower, more stable clock source when they are seen. If your system supports TSC time but doesn’t default to that, it may be disabled for a good reason. And some operating systems may not detect all the possible problems correctly, or will allow using TSC even in situations where it’s known to be inaccurate.

The High Precision Event Timer (HPET) is the preferred timer on systems where it’s available and TSC is not accurate. The timer chip itself is programmable to allow up to 100 nanosecond resolution, but you may not see that much accuracy in your system clock.

Advanced Configuration and Power Interface (ACPI) provides a Power Management (PM) Timer, which Linux refers to as the acpi_pm. The clock derived from acpi_pm will at best provide 300 nanosecond resolution.

Timers used on older PC hardware include the 8254 Programmable Interval Timer (PIT), the real-time clock (RTC), the Advanced Programmable Interrupt Controller (APIC) timer, and the Cyclone timer. These timers aim for millisecond resolution.

EXPLAIN
**pg_upgrade**

**Name**

pg_upgrade — upgrade a PostgreSQL server instance

**Synopsis**

pg_upgrade -b oldbindir -B newbindir -d olddatadir -D newdatadir [option...]

**Description**

pg_upgrade (formerly called pg_migrator) allows data stored in PostgreSQL data files to be upgraded to a later PostgreSQL major version without the data dump/reload typically required for major version upgrades, e.g. from 8.4.7 to the current major release of PostgreSQL. It is not required for minor version upgrades, e.g. from 9.0.1 to 9.0.4.

Major PostgreSQL releases regularly add new features that often change the layout of the system tables, but the internal data storage format rarely changes. pg_upgrade uses this fact to perform rapid upgrades by creating new system tables and simply reusing the old user data files. If a future major release ever changes the data storage format in a way that makes the old data format unreadable, pg_upgrade will not be usable for such upgrades. (The community will attempt to avoid such situations.)

pg_upgrade does its best to make sure the old and new clusters are binary-compatible, e.g. by checking for compatible compile-time settings, including 32/64-bit binaries. It is important that any external modules are also binary compatible, though this cannot be checked by pg_upgrade.

pg_upgrade supports upgrades from 8.4.X and later to the current major release of PostgreSQL, including snapshot and alpha releases.

**Options**

pg_upgrade accepts the following command-line arguments:

- `-b bindir`
  --old-bindir=bindir
  the old PostgreSQL executable directory; environment variable PGINOLD

- `-B bindir`
  --new-bindir=bindir
  the new PostgreSQL executable directory; environment variable PGINNEW

- `-c`
  --check
  check clusters only, don’t change any data
pg_upgrade

-d datadir
    --old-datadir=datadir
    the old cluster data directory; environment variable PGDATAOLD

-D datadir
    --new-datadir=datadir
    the new cluster data directory; environment variable PGDATERNEW

-j
    --jobs
    number of simultaneous processes or threads to use

-k
    --link
    use hard links instead of copying files to the new cluster

-o options
    --old-options options
    options to be passed directly to the old postgres command; multiple option invocations are appended

-O options
    --new-options options
    options to be passed directly to the new postgres command; multiple option invocations are appended

-p port
    --old-port=port
    the old cluster port number; environment variable PGPORTOLD

-P port
    --new-port=port
    the new cluster port number; environment variable PGPORTNEW

-r
    --retain
    retain SQL and log files even after successful completion

-U username
    --username=username
    cluster’s install user name; environment variable PGUSER

-v
    --verbose
    enable verbose internal logging

-V
    --version
    display version information, then exit

-?
    --help
    show help, then exit
### Usage

These are the steps to perform an upgrade with `pg_upgrade`:

1. **Optionally move the old cluster**
   
   If you are using a version-specific installation directory, e.g. `/opt/PostgreSQL/9.1`, you do not need to move the old cluster. The graphical installers all use version-specific installation directories.

   If your installation directory is not version-specific, e.g. `/usr/local/pgsql`, it is necessary to move the current PostgreSQL install directory so it does not interfere with the new PostgreSQL installation. Once the current PostgreSQL server is shut down, it is safe to rename the PostgreSQL installation directory; assuming the old directory is `/usr/local/pgsql`, you can do:

   ```bash
   mv /usr/local/pgsql /usr/local/pgsql.old
   ```

2. **For source installs, build the new version**

   Build the new PostgreSQL source with `configure` flags that are compatible with the old cluster. `pg_upgrade` will check `pg_controldata` to make sure all settings are compatible before starting the upgrade.

3. **Install the new PostgreSQL binaries**

   Install the new server’s binaries and support files. `pg_upgrade` is included in a default installation. For source installs, if you wish to install the new server in a custom location, use the `prefix` variable:

   ```bash
   make prefix=/usr/local/pgsql.new install
   ```

4. **Initialize the new PostgreSQL cluster**

   Initialize the new cluster using `initdb`. Again, use compatible `initdb` flags that match the old cluster. Many prebuilt installers do this step automatically. There is no need to start the new cluster.

5. **Install custom shared object files**

   Install any custom shared object files (or DLLs) used by the old cluster into the new cluster, e.g. `pgcrypto.so`, whether they are from `contrib` or some other source. Do not install the schema definitions, e.g. `CREATE EXTENSION pgcrypto`, because these will be upgraded from the old cluster. Also, any custom full text search files (dictionary, synonym, thesaurus, stop words) must also be copied to the new cluster.

6. **Adjust authentication**

   `pg_upgrade` will connect to the old and new servers several times, so you might want to set authentication to `peer` in `pg_hba.conf` or use a `~/.pgpass` file (see Section 32.15).

7. **Stop both servers**

   Make sure both database servers are stopped using, on Unix, e.g.:

   ```bash
   pg_ctl -D /opt/PostgreSQL/8.4 stop
   pg_ctl -D /opt/PostgreSQL/9.0 stop
   ```

   or on Windows, using the proper service names:

   ```bash
   NET STOP postgresql-8.4
   NET STOP postgresql-9.0
   ```

   Streaming replication and log-shipping standby servers can remain running until a later step.
8. Prepare for standby server upgrades

If you are upgrading standby servers using methods outlined in section step 10, verify that the old standby servers are caught up by running `pg_controldata` against the old primary and standby clusters. Verify that the “Latest checkpoint location” values match in all clusters. (There will be a mismatch if old standby servers were shut down before the old primary or if the old standby servers are still running.) Also, change `wal_level` to `replica` in the `postgresql.conf` file on the new primary cluster.

9. Run `pg_upgrade`

Always run the `pg_upgrade` binary of the new server, not the old one. `pg_upgrade` requires the specification of the old and new cluster’s data and executable (bin) directories. You can also specify user and port values, and whether you want the data linked instead of copied (the default).

If you use link mode, the upgrade will be much faster (no file copying) and use less disk space, but you will not be able to access your old cluster once you start the new cluster after the upgrade. Link mode also requires that the old and new cluster data directories be in the same file system. (Tablespaces and `pg_xlog` can be on different file systems.) See `pg_upgrade --help` for a full list of options.

The `--jobs` option allows multiple CPU cores to be used for copying/linking of files and to dump and reload database schemas in parallel; a good place to start is the maximum of the number of CPU cores and tablespaces. This option can dramatically reduce the time to upgrade a multi-database server running on a multiprocessor machine.

For Windows users, you must be logged into an administrative account, and then start a shell as the `postgres` user and set the proper path:

```bash
RUNAS /USER:postgres "CMD.EXE"
SET PATH=%PATH%;C:\Program Files\PostgreSQL\9.0\bin;
```

and then run `pg_upgrade` with quoted directories, e.g.:

```bash
pg_upgrade.exe
--old-datadir "C:/Program Files/PostgreSQL/8.4/data"
--new-datadir "C:/Program Files/PostgreSQL/9.0/data"
--old-bindir "C:/Program Files/PostgreSQL/8.4/bin"
--new-bindir "C:/Program Files/PostgreSQL/9.0/bin"
```

Once started, `pg_upgrade` will verify the two clusters are compatible and then do the upgrade. You can use `pg_upgrade --check` to perform only the checks, even if the old server is still running. `pg_upgrade --check` will also outline any manual adjustments you will need to make after the upgrade. If you are going to be using link mode, you should use the `--link` option with `--check` to enable link-mode-specific checks. `pg_upgrade` requires write permission in the current directory.

Obviously, no one should be accessing the clusters during the upgrade. `pg_upgrade` defaults to running servers on port 50432 to avoid unintended client connections. You can use the same port number for both clusters when doing an upgrade because the old and new clusters will not be running at the same time. However, when checking an old running server, the old and new port numbers must be different.

If an error occurs while restoring the database schema, `pg_upgrade` will exit and you will have to revert to the old cluster as outlined in step 16 below. To try `pg_upgrade` again, you will need to modify the old cluster so the `pg_upgrade` schema restore succeeds. If the problem is a `contrib` module, you might need to uninstall the `contrib` module from the old cluster and install it in the new cluster after the upgrade, assuming the module is not being used to store user data.

10. Upgrade Streaming Replication and Log-Shipping standby servers
If you used link mode and have Streaming Replication (see Section 26.2.5) or Log-Shipping (see Section 26.2) standby servers, you can follow these steps to quickly upgrade them. You will not be running pg_upgrade on the standby servers, but rather rsync on the primary. Do not start any servers yet.

If you did not use link mode, do not have or do not want to use rsync, or want an easier solution, skip the instructions in this section and simply recreate the standby servers once pg_upgrade completes and the new primary is running.

a. Install the new PostgreSQL binaries on standby servers
   Make sure the new binaries and support files are installed on all standby servers.

b. Make sure the new standby data directories do not exist
   Make sure the new standby data directories do not exist or are empty. If initdb was run, delete the standby servers’ new data directories.

c. Install custom shared object files
   Install the same custom shared object files on the new standbys that you installed in the new primary cluster.

d. Stop standby servers
   If the standby servers are still running, stop them now using the above instructions.

e. Save configuration files
   Save any configuration files from the old standbys’ data directories you need to keep, e.g. postgresql.conf, recovery.conf, because these will be overwritten or removed in the next step.

f. Run rsync
   When using link mode, standby servers can be quickly upgraded using rsync. To accomplish this, from a directory on the primary server that is above the old and new database cluster directories, run this on the primary for each standby server:
   ```
   rsync --archive --delete --hard-links --size-only --no-inc-recursive old_cluster
   where old_cluster and new_cluster are relative to the current directory on the primary, and remote_dir is above the old and new cluster directories on the standby. The directory structure under the specified directories on the primary and standbys must match. Consult the rsync manual page for details on specifying the remote directory, e.g.
   rsync --archive --delete --hard-links --size-only --no-inc-recursive /opt/PostgreSQL/9.6 standby.example.com:/opt/PostgreSQL
   You can verify what the command will do using rsync’s --dry-run option. While rsync must be run on the primary for at least one standby, it is possible to run rsync on an upgraded standby to upgrade other standbys, as long as the upgraded standby has not been started.
   What this does is to record the links created by pg_upgrade’s link mode that connect files in the old and new clusters on the primary server. It then finds matching files in the standby’s old cluster and creates links for them in the standby’s new cluster. Files that were not linked on the primary are copied from the primary to the standby. (They are usually small.) This provides rapid standby upgrades. Unfortunately, rsync needlessly copies files associated with temporary and unlogged tables because these files don’t normally exist on standby servers.
   If you have tablespaces, you will need to run a similar rsync command for each tablespace directory, e.g.:
rsync --archive --delete --hard-links --size-only --no-inc-recursive /voll/pg_tblsp/PG_9.5_201510051 /voll/pg_tblsp/PG_9.6_201608131 standby.example.com:/voll/pg_tblsp

If you have relocated pg_xlog outside the data directories, rsync must be run on those directories too.

g. Configure streaming replication and log-shipping standby servers

Configure the servers for log shipping. (You do not need to run pg_start_backup() and pg_stop_backup() or take a file system backup as the standbys are still synchronized with the primary.)

11. Restore pg_hba.conf

If you modified pg_hba.conf, restore its original settings. It might also be necessary to adjust other configuration files in the new cluster to match the old cluster, e.g. postgresql.conf.

12. Start the new server

The new server can now be safely started, and then any rsync’ed standby servers.

13. Post-Upgrade processing

If any post-upgrade processing is required, pg_upgrade will issue warnings as it completes. It will also generate script files that must be run by the administrator. The script files will connect to each database that needs post-upgrade processing. Each script should be run using:

cat script.sql

The scripts can be run in any order and can be deleted once they have been run.

Caution

In general it is unsafe to access tables referenced in rebuild scripts until the rebuild scripts have run to completion; doing so could yield incorrect results or poor performance. Tables not referenced in rebuild scripts can be accessed immediately.

14. Statistics

Because optimizer statistics are not transferred by pg_upgrade, you will be instructed to run a command to regenerate that information at the end of the upgrade. You might need to set connection parameters to match your new cluster.

15. Delete old cluster

Once you are satisfied with the upgrade, you can delete the old cluster’s data directories by running the script mentioned when pg_upgrade completes. (Automatic deletion is not possible if you have user-defined tablespaces inside the old data directory.) You can also delete the old installation directories (e.g. bin, share).

16. Reverting to old cluster

If, after running pg_upgrade, you wish to revert to the old cluster, there are several options:

- If the --check option was used, the old cluster was unmodified; it can be restarted.
- If the --link option was not used, the old cluster was unmodified; it can be restarted.
- If the --link option was used, the data files might be shared between the old and new cluster:
  - If pg_upgrade aborted before linking started, the old cluster was unmodified; it can be restarted.
  - If you did not start the new cluster, the old cluster was unmodified except that, when linking started, a .old suffix was appended to $PGDATA/global/pg_control. To reuse the old
cluster, remove the .old suffix from $PGDATA/global/pg_control; you can then restart the old cluster.

- If you did start the new cluster, it has written to shared files and it is unsafe to use the old cluster. The old cluster will need to be restored from backup in this case.

Notes

pg_upgrade does not support upgrading of databases containing these reg* OID-referencing system data types: regproc, regprocedure, regoper, regoperator, regconfig, and regdictionary. (regtype can be upgraded.)

All failure, rebuild, and reindex cases will be reported by pg_upgrade if they affect your installation; post-upgrade scripts to rebuild tables and indexes will be generated automatically. If you are trying to automate the upgrade of many clusters, you should find that clusters with identical database schemas require the same post-upgrade steps for all cluster upgrades; this is because the post-upgrade steps are based on the database schemas, and not user data.

For deployment testing, create a schema-only copy of the old cluster, insert dummy data, and upgrade that.

If you are upgrading a pre-PostgreSQL 9.2 cluster that uses a configuration-file-only directory, you must pass the real data directory location to pg_upgrade, and pass the configuration directory location to the server, e.g. -d /real-data-directory -o '-D /configuration-directory'.

If using a pre-9.1 old server that is using a non-default Unix-domain socket directory or a default that differs from the default of the new cluster, set PGHOST to point to the old server’s socket location. (This is not relevant on Windows.)

If you want to use link mode and you do not want your old cluster to be modified when the new cluster is started, make a copy of the old cluster and upgrade that in link mode. To make a valid copy of the old cluster, use rsync to create a dirty copy of the old cluster while the server is running, then shut down the old server and run rsync --checksum again to update the copy with any changes to make it consistent. (--checksum is necessary because rsync only has file modification-time granularity of one second.) You might want to exclude some files, e.g. postmaster.pid, as documented in Section 25.3.3. If your file system supports file system snapshots or copy-on-write file copies, you can use that to make a backup of the old cluster and tablespaces, though the snapshot and copies must be created simultaneously or while the database server is down.

initdb, pg_ctl, pg_dump, postgres
**pg_xlogdump**

**Name**

**pg_xlogdump** — display a human-readable rendering of the write-ahead log of a PostgreSQL database cluster

**Synopsis**

```
pg_xlogdump [option...][startseg [endseg]]
```

**Description**

**pg_xlogdump** displays the write-ahead log (WAL) and is mainly useful for debugging or educational purposes.

This utility can only be run by the user who installed the server, because it requires read-only access to the data directory.

**Options**

The following command-line options control the location and format of the output:

- **startseg**
  
  Start reading at the specified log segment file. This implicitly determines the path in which files will be searched for, and the timeline to use.

- **endseg**
  
  Stop after reading the specified log segment file.

- **-b**
  
  **--byp-file**

  Output detailed information about backup blocks.

- **-e end**
  
  **--end=end**

  Stop reading at the specified log position, instead of reading to the end of the log stream.

- **-f**
  
  **--follow**

  After reaching the end of valid WAL, keep polling once per second for new WAL to appear.

- **-n limit**
  
  **--limit=limit**

  Display the specified number of records, then stop.
pg_xlogdump

-p path
--path=path

Specifies a directory to search for log segment files or a directory with a \texttt{pg\_xlog} subdirectory that contains such files. The default is to search in the current directory, the \texttt{pg\_xlog} subdirectory of the current directory, and the \texttt{pg\_xlog} subdirectory of \texttt{PGDATA}.

-r rmgr
--rmgr=rmgr

Only display records generated by the specified resource manager. If \texttt{list} is passed as name, print a list of valid resource manager names, and exit.

-s start
--start=start

Log position at which to start reading. The default is to start reading the first valid log record found in the earliest file found.

-t timeline
--timeline=timeline

Timeline from which to read log records. The default is to use the value in \texttt{startseg}, if that is specified; otherwise, the default is 1.

-V
--version

Print the \texttt{pg\_xlogdump} version and exit.

-x xid
--xid=xid

Only display records marked with the given transaction ID.

-z
--stats[=record]

Display summary statistics (number and size of records and full-page images) instead of individual records. Optionally generate statistics per-record instead of per-rmgr.

-?
--help

Show help about \texttt{pg\_xlogdump} command line arguments, and exit.

\section*{Notes}

Can give wrong results when the server is running.

Only the specified timeline is displayed (or the default, if none is specified). Records in other timelines are ignored.

\texttt{pg\_xlogdump} cannot read WAL files with suffix \texttt{.partial}. If those files need to be read, \texttt{.partial} suffix needs to be removed from the file name.

Section 30.5
postgres

Name

postgres — PostgreSQL database server

Synopsis

postgres [option...]

Description

postgres is the PostgreSQL database server. In order for a client application to access a database it connects (over a network or locally) to a running postgres instance. The postgres instance then starts a separate server process to handle the connection.

One postgres instance always manages the data of exactly one database cluster. A database cluster is a collection of databases that is stored at a common file system location (the “data area”). More than one postgres instance can run on a system at one time, so long as they use different data areas and different communication ports (see below). When postgres starts it needs to know the location of the data area. The location must be specified by the -D option or the PGDATA environment variable; there is no default. Typically, -D or PGDATA points directly to the data area directory created by initdb. Other possible file layouts are discussed in Section 19.2.

By default postgres starts in the foreground and prints log messages to the standard error stream. In practical applications postgres should be started as a background process, perhaps at boot time.

The postgres command can also be called in single-user mode. The primary use for this mode is during bootstrapping by initdb. Sometimes it is used for debugging or disaster recovery; note that running a single-user server is not truly suitable for debugging the server, since no realistic interprocess communication and locking will happen. When invoked in single-user mode from the shell, the user can enter queries and the results will be printed to the screen, but in a form that is more useful for developers than end users. In the single-user mode, the session user will be set to the user with ID 1, and implicit superuser powers are granted to this user. This user does not actually have to exist, so the single-user mode can be used to manually recover from certain kinds of accidental damage to the system catalogs.

Options

postgres accepts the following command-line arguments. For a detailed discussion of the options consult Chapter 19. You can save typing most of these options by setting up a configuration file. Some (safe) options can also be set from the connecting client in an application-dependent way to apply only for that session. For example, if the environment variable PGOPTIONS is set, then libpq-based clients will pass that string to the server, which will interpret it as postgres command-line options.
General Purpose

-B nbuffers

Sets the number of shared buffers for use by the server processes. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the shared_buffers configuration parameter.

-c name=value

Sets a named run-time parameter. The configuration parameters supported by PostgreSQL are described in Chapter 19. Most of the other command line options are in fact short forms of such a parameter assignment. -c can appear multiple times to set multiple parameters.

-C name

Prints the value of the named run-time parameter, and exits. (See the -c option above for details.) This can be used on a running server, and returns values from postgresql.conf, modified by any parameters supplied in this invocation. It does not reflect parameters supplied when the cluster was started.

This option is meant for other programs that interact with a server instance, such as pg_ctl, to query configuration parameter values. User-facing applications should instead use SHOW or the pg_settings view.

-d debug-level

Sets the debug level. The higher this value is set, the more debugging output is written to the server log. Values are from 1 to 5. It is also possible to pass -d 0 for a specific session, which will prevent the server log level of the parent postgres process from being propagated to this session.

-D datadir

Specifies the file system location of the database configuration files. See Section 19.2 for details.

-e

Sets the default date style to “European”, that is DMY ordering of input date fields. This also causes the day to be printed before the month in certain date output formats. See Section 8.5 for more information.

-F

Disables fsync calls for improved performance, at the risk of data corruption in the event of a system crash. Specifying this option is equivalent to disabling the fsync configuration parameter. Read the detailed documentation before using this!

-h hostname

Specifies the IP host name or address on which postgres is to listen for TCP/IP connections from client applications. The value can also be a comma-separated list of addresses, or * to specify listening on all available interfaces. An empty value specifies not listening on any IP addresses, in which case only Unix-domain sockets can be used to connect to the server. Defaults to listening only on localhost. Specifying this option is equivalent to setting the listen_addresses configuration parameter.

-i

Allows remote clients to connect via TCP/IP (Internet domain) connections. Without this option, only local connections are accepted. This option is equivalent to setting listen_addresses to * in postgresql.conf or via -h.
This option is deprecated since it does not allow access to the full functionality of listen_addresses. It’s usually better to set listen_addresses directly.

-k directory

Specifies the directory of the Unix-domain socket on which postgres is to listen for connections from client applications. The value can also be a comma-separated list of directories. An empty value specifies not listening on any Unix-domain sockets, in which case only TCP/IP sockets can be used to connect to the server. The default value is normally /tmp, but that can be changed at build time. Specifying this option is equivalent to setting the unix_socket_directories configuration parameter.

-l

Enables secure connections using SSL. PostgreSQL must have been compiled with support for SSL for this option to be available. For more information on using SSL, refer to Section 18.9.

-N max-connections

Sets the maximum number of client connections that this server will accept. The default value of this parameter is chosen automatically by initdb. Specifying this option is equivalent to setting the max_connections configuration parameter.

-o extra-options

The command-line-style arguments specified in extra-options are passed to all server processes started by this postgres process.

Spaces within extra-options are considered to separate arguments, unless escaped with a backslash (\); write \ to represent a literal backslash. Multiple arguments can also be specified via multiple uses of -o.

The use of this option is obsolete; all command-line options for server processes can be specified directly on the postgres command line.

-p port

Specifies the TCP/IP port or local Unix domain socket file extension on which postgres is to listen for connections from client applications. Defaults to the value of the PGPORT environment variable, or if PGPORT is not set, then defaults to the value established during compilation (normally 5432). If you specify a port other than the default port, then all client applications must specify the same port using either command-line options or PGPORT.

-s

Print time information and other statistics at the end of each command. This is useful for benchmarking or for use in tuning the number of buffers.

-S work_mem

Specifies the amount of memory to be used by internal sorts and hashes before resorting to temporary disk files. See the description of the work_mem configuration parameter in Section 19.4.1.

-V

--version

Print the postgres version and exit.

--name=value

Sets a named run-time parameter; a shorter form of -c.
--describe-config

This option dumps out the server’s internal configuration variables, descriptions, and defaults in tab-delimited COPY format. It is designed primarily for use by administration tools.

-?
--help

Show help about postgres command line arguments, and exit.

Semi-internal Options

The options described here are used mainly for debugging purposes, and in some cases to assist with recovery of severely damaged databases. There should be no reason to use them in a production database setup. They are listed here only for use by PostgreSQL system developers. Furthermore, these options might change or be removed in a future release without notice.

-f { s | i | o | b | t | n | m | h }

Forbids the use of particular scan and join methods: s and i disable sequential and index scans respectively, o, b and t disable index-only scans, bitmap index scans, and TID scans respectively, while n, m, and h disable nested-loop, merge and hash joins respectively.

Neither sequential scans nor nested-loop joins can be disabled completely; the -fs and -fn options simply discourage the optimizer from using those plan types if it has any other alternative.

-n

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that postgres will not reinitialize shared data structures. A knowledgeable system programmer can then use a debugger to examine shared memory and semaphore state.

-O

Allows the structure of system tables to be modified. This is used by initdb.

-P

Ignore system indexes when reading system tables, but still update the indexes when modifying the tables. This is useful when recovering from damaged system indexes.

-t pa[rser] | pl[anner] | e[xecutor]

Print timing statistics for each query relating to each of the major system modules. This option cannot be used together with the -s option.

-T

This option is for debugging problems that cause a server process to die abnormally. The ordinary strategy in this situation is to notify all other server processes that they must terminate and then reinitialize the shared memory and semaphores. This is because an errant server process could have corrupted some shared state before terminating. This option specifies that postgres will stop all other server processes by sending the signal SIGSTOP, but will not cause them to terminate. This permits system programmers to collect core dumps from all server processes by hand.
-v protocol
   Specifies the version number of the frontend/backend protocol to be used for a particular session. This option is for internal use only.

-W seconds
   A delay of this many seconds occurs when a new server process is started, after it conducts the authentication procedure. This is intended to give an opportunity to attach to the server process with a debugger.

Options for Single-User Mode
The following options only apply to the single-user mode (see Single-User Mode).

--single
   Selects the single-user mode. This must be the first argument on the command line.

database
   Specifies the name of the database to be accessed. This must be the last argument on the command line. If it is omitted it defaults to the user name.

-E
   Echo all commands to standard output before executing them.

-j
   Use semicolon followed by two newlines, rather than just newline, as the command entry terminator.

-r filename
   Send all server log output to filename. This option is only honored when supplied as a command-line option.

Environment

PGCLIENTENCODING
   Default character encoding used by clients. (The clients can override this individually.) This value can also be set in the configuration file.

PGDATA
   Default data directory location

PGDATESTYLE
   Default value of the DateStyle run-time parameter. (The use of this environment variable is deprecated.)

PGPORT
   Default port number (preferably set in the configuration file)
Diagnostics

A failure message mentioning `semget` or `shmget` probably indicates you need to configure your kernel to provide adequate shared memory and semaphores. For more discussion see Section 18.4. You might be able to postpone reconfiguring your kernel by decreasing `shared_buffers` to reduce the shared memory consumption of PostgreSQL, and/or by reducing `max_connections` to reduce the semaphore consumption.

A failure message suggesting that another server is already running should be checked carefully, for example by using the command

```
$ ps ax | grep postgres
```

or

```
$ ps -ef | grep postgres
```

depending on your system. If you are certain that no conflicting server is running, you can remove the lock file mentioned in the message and try again.

A failure message indicating inability to bind to a port might indicate that that port is already in use by some non-PostgreSQL process. You might also get this error if you terminate `postgres` and immediately restart it using the same port; in this case, you must simply wait a few seconds until the operating system closes the port before trying again. Finally, you might get this error if you specify a port number that your operating system considers to be “trusted” and only permit the Unix superuser to access them.

Notes

The utility command `pg_ctl` can be used to start and shut down the `postgres` server safely and comfortably.

If at all possible, do not use `SIGKILL` to kill the main `postgres` server. Doing so will prevent `postgres` from freeing the system resources (e.g., shared memory and semaphores) that it holds before terminating. This might cause problems for starting a fresh `postgres` run.

To terminate the `postgres` server normally, the signals `SIGTERM`, `SIGINT`, or `SIGQUIT` can be used. The first will wait for all clients to terminate before quitting, the second will forcefully disconnect all clients, and the third will quit immediately without proper shutdown, resulting in a recovery run during restart.

The `SIGHUP` signal will reload the server configuration files. It is also possible to send `SIGHUP` to an individual server process, but that is usually not sensible.

To cancel a running query, send the `SIGINT` signal to the process running that command. To terminate a backend process cleanly, send `SIGTERM` to that process. See also `pg_cancel_backend` and `pg_terminate_backend` in Section 9.26.2 for the SQL-callable equivalents of these two actions.

The `postgres` server uses `SIGQUIT` to tell subordinate server processes to terminate without normal cleanup. This signal should not be used by users. It is also unwise to send `SIGKILL` to a server process — the main `postgres` process will interpret this as a crash and will force all the sibling processes to quit as part of its standard crash-recovery procedure.
Bugs

The -- options will not work on FreeBSD or OpenBSD. Use -c instead. This is a bug in the affected operating systems; a future release of PostgreSQL will provide a workaround if this is not fixed.

Single-User Mode

To start a single-user mode server, use a command like

```
postgres --single -D /usr/local/pgsql/data other-options my_database
```

Provide the correct path to the database directory with -D, or make sure that the environment variable PGDATA is set. Also specify the name of the particular database you want to work in.

Normally, the single-user mode server treats newline as the command entry terminator; there is no intelligence about semicolons, as there is in psql. To continue a command across multiple lines, you must type backslash just before each newline except the last one. The backslash and adjacent newline are both dropped from the input command. Note that this will happen even when within a string literal or comment.

But if you use the -j command line switch, a single newline does not terminate command entry; instead, the sequence semicolon-newline-newline-newline does. That is, type a semicolon immediately followed by a completely empty line. Backslash-newline is not treated specially in this mode. Again, there is no intelligence about such a sequence appearing within a string literal or comment.

In either input mode, if you type a semicolon that is not just before or part of a command entry terminator, it is considered a command separator. When you do type a command entry terminator, the multiple statements you’ve entered will be executed as a single transaction.

To quit the session, type EOF (Control+D, usually). If you’ve entered any text since the last command entry terminator, then EOF will be taken as a command entry terminator, and another EOF will be needed to exit.

Note that the single-user mode server does not provide sophisticated line-editing features (no command history, for example). Single-user mode also does not do any background processing, such as automatic checkpoints or replication.

Examples

To start postgres in the background using default values, type:

```
$ nohup postgres >logfile 2>&1 < /dev/null &
```

To start postgres with a specific port, e.g. 1234:

```
$ postgres -p 1234
```

To connect to this server using psql, specify this port with the -p option:

```
$ psql -p 1234
```

or set the environment variable PGPORT:

```
$ export PGPORT=1234
```
Named run-time parameters can be set in either of these styles:

```bash
$ postgres -c work_mem=1234
$ postgres --work_mem=1234
```

Either form overrides whatever setting might exist for `work_mem` in `postgresql.conf`. Notice that underscores in parameter names can be written as either underscore or dash on the command line. Except for short-term experiments, it's probably better practice to edit the setting in `postgresql.conf` than to rely on a command-line switch to set a parameter.

VII. Internals

This part contains assorted information that might be of use to PostgreSQL developers.
Chapter 49. Overview of PostgreSQL Internals

Author: This chapter originated as part of Enhancement of the ANSI SQL Implementation of PostgreSQL, Stefan Simkovics’ Master’s Thesis prepared at Vienna University of Technology under the direction of O.Univ.Prof.Dr. Georg Gottlob and Univ.Ass. Mag. Katrin Seyr.

This chapter gives an overview of the internal structure of the backend of PostgreSQL. After having read the following sections you should have an idea of how a query is processed. This chapter does not aim to provide a detailed description of the internal operation of PostgreSQL, as such a document would be very extensive. Rather, this chapter is intended to help the reader understand the general sequence of operations that occur within the backend from the point at which a query is received, to the point at which the results are returned to the client.

49.1. The Path of a Query

Here we give a short overview of the stages a query has to pass in order to obtain a result.

1. A connection from an application program to the PostgreSQL server has to be established. The application program transmits a query to the server and waits to receive the results sent back by the server.

2. The parser stage checks the query transmitted by the application program for correct syntax and creates a query tree.

3. The rewrite system takes the query tree created by the parser stage and looks for any rules (stored in the system catalogs) to apply to the query tree. It performs the transformations given in the rule bodies.

   One application of the rewrite system is in the realization of views. Whenever a query against a view (i.e., a virtual table) is made, the rewrite system rewrites the user’s query to a query that accesses the base tables given in the view definition instead.

4. The planner/optimizer takes the (rewritten) query tree and creates a query plan that will be the input to the executor.

   It does so by first creating all possible paths leading to the same result. For example if there is an index on a relation to be scanned, there are two paths for the scan. One possibility is a simple sequential scan and the other possibility is to use the index. Next the cost for the execution of each path is estimated and the cheapest path is chosen. The cheapest path is expanded into a complete plan that the executor can use.

5. The executor recursively steps through the plan tree and retrieves rows in the way represented by the plan. The executor makes use of the storage system while scanning relations, performs sorts and joins, evaluates qualifications and finally hands back the rows derived.

In the following sections we will cover each of the above listed items in more detail to give a better understanding of PostgreSQL’s internal control and data structures.
Chapter 49. Overview of PostgreSQL Internals

49.2. How Connections are Established

PostgreSQL is implemented using a simple “process per user” client/server model. In this model there is one client process connected to exactly one server process. As we do not know ahead of time how many connections will be made, we have to use a master process that spawns a new server process every time a connection is requested. This master process is called postgres and listens at a specified TCP/IP port for incoming connections. Whenever a request for a connection is detected the postgres process spawns a new server process. The server tasks communicate with each other using semaphores and shared memory to ensure data integrity throughout concurrent data access.

The client process can be any program that understands the PostgreSQL protocol described in Chapter 51. Many clients are based on the C-language library libpq, but several independent implementations of the protocol exist, such as the Java JDBC driver.

Once a connection is established the client process can send a query to the backend (server). The query is transmitted using plain text, i.e., there is no parsing done in the frontend (client). The server parses the query, creates an execution plan, executes the plan and returns the retrieved rows to the client by transmitting them over the established connection.

49.3. The Parser Stage

The parser stage consists of two parts:

- The parser defined in gram.y and scan.l is built using the Unix tools bison and flex.
- The transformation process does modifications and augmentations to the data structures returned by the parser.

49.3.1. Parser

The parser has to check the query string (which arrives as plain text) for valid syntax. If the syntax is correct a parse tree is built up and handed back; otherwise an error is returned. The parser and lexer are implemented using the well-known Unix tools bison and flex. The lexer is defined in the file scan.l and is responsible for recognizing identifiers, the SQL key words etc. For every key word or identifier that is found, a token is generated and handed to the parser.

The parser is defined in the file gram.y and consists of a set of grammar rules and actions that are executed whenever a rule is fired. The code of the actions (which is actually C code) is used to build up the parse tree.

The file scan.l is transformed to the C source file scan.c using the program flex and gram.y is transformed to gram.c using bison. After these transformations have taken place a normal C compiler can be used to create the parser. Never make any changes to the generated C files as they will be overwritten the next time flex or bison is called.

Note: The mentioned transformations and compilations are normally done automatically using the makefiles shipped with the PostgreSQL source distribution.
A detailed description of bison or the grammar rules given in gram.y would be beyond the scope of this paper. There are many books and documents dealing with flex and bison. You should be familiar with bison before you start to study the grammar given in gram.y otherwise you won’t understand what happens there.

49.3.2. Transformation Process

The parser stage creates a parse tree using only fixed rules about the syntactic structure of SQL. It does not make any lookups in the system catalogs, so there is no possibility to understand the detailed semantics of the requested operations. After the parser completes, the transformation process takes the tree handed back by the parser as input and does the semantic interpretation needed to understand which tables, functions, and operators are referenced by the query. The data structure that is built to represent this information is called the query tree.

The reason for separating raw parsing from semantic analysis is that system catalog lookups can only be done within a transaction, and we do not wish to start a transaction immediately upon receiving a query string. The raw parsing stage is sufficient to identify the transaction control commands (BEGIN, ROLLBACK, etc), and these can then be correctly executed without any further analysis. Once we know that we are dealing with an actual query (such as SELECT or UPDATE), it is okay to start a transaction if we’re not already in one. Only then can the transformation process be invoked.

The query tree created by the transformation process is structurally similar to the raw parse tree in most places, but it has many differences in detail. For example, a FuncCall node in the parse tree represents something that looks syntactically like a function call. This might be transformed to either a FuncExpr or Aggref node depending on whether the referenced name turns out to be an ordinary function or an aggregate function. Also, information about the actual data types of columns and expression results is added to the query tree.

49.4. The PostgreSQL Rule System

PostgreSQL supports a powerful rule system for the specification of views and ambiguous view updates. Originally the PostgreSQL rule system consisted of two implementations:

- The first one worked using row level processing and was implemented deep in the executor. The rule system was called whenever an individual row had been accessed. This implementation was removed in 1995 when the last official release of the Berkeley Postgres project was transformed into Postgres95.

- The second implementation of the rule system is a technique called query rewriting. The rewrite system is a module that exists between the parser stage and the planner/optimizer. This technique is still implemented.

The query rewriter is discussed in some detail in Chapter 39, so there is no need to cover it here. We will only point out that both the input and the output of the rewriter are query trees, that is, there is no change in the representation or level of semantic detail in the trees. Rewriting can be thought of as a form of macro expansion.
49.5. Planner/Optimizer

The task of the planner/optimizer is to create an optimal execution plan. A given SQL query (and hence, a query tree) can be actually executed in a wide variety of different ways, each of which will produce the same set of results. If it is computationally feasible, the query optimizer will examine each of these possible execution plans, ultimately selecting the execution plan that is expected to run the fastest.

**Note:** In some situations, examining each possible way in which a query can be executed would take an excessive amount of time and memory space. In particular, this occurs when executing queries involving large numbers of join operations. In order to determine a reasonable (not necessarily optimal) query plan in a reasonable amount of time, PostgreSQL uses a Genetic Query Optimizer (see Chapter 58) when the number of joins exceeds a threshold (see geqo_threshold).

The planner’s search procedure actually works with data structures called paths, which are simply cut-down representations of plans containing only as much information as the planner needs to make its decisions. After the cheapest path is determined, a full-fledged plan tree is built to pass to the executor. This represents the desired execution plan in sufficient detail for the executor to run it. In the rest of this section we’ll ignore the distinction between paths and plans.

49.5.1. Generating Possible Plans

The planner/optimizer starts by generating plans for scanning each individual relation (table) used in the query. The possible plans are determined by the available indexes on each relation. There is always the possibility of performing a sequential scan on a relation, so a sequential scan plan is always created. Assume an index is defined on a relation (for example a B-tree index) and a query contains the restriction relation.attribute OPR constant. If relation.attribute happens to match the key of the B-tree index and OPR is one of the operators listed in the index’s operator class, another plan is created using the B-tree index to scan the relation. If there are further indexes present and the restrictions in the query happen to match a key of an index, further plans will be considered. Index scan plans are also generated for indexes that have a sort ordering that can match the query’s ORDER BY clause (if any), or a sort ordering that might be useful for merge joining (see below).

If the query requires joining two or more relations, plans for joining relations are considered after all feasible plans have been found for scanning single relations. The three available join strategies are:

- **nested loop join:** The right relation is scanned once for every row found in the left relation. This strategy is easy to implement but can be very time consuming. (However, if the right relation can be scanned with an index scan, this can be a good strategy. It is possible to use values from the current row of the left relation as keys for the index scan of the right.)

- **merge join:** Each relation is sorted on the join attributes before the join starts. Then the two relations are scanned in parallel, and matching rows are combined to form join rows. This kind of join is more attractive because each relation has to be scanned only once. The required sorting might be achieved either by an explicit sort step, or by scanning the relation in the proper order using an index on the join key.

- **hash join:** the right relation is first scanned and loaded into a hash table, using its join attributes as hash keys. Next the left relation is scanned and the appropriate values of every row found are used as hash keys to locate the matching rows in the table.
When the query involves more than two relations, the final result must be built up by a tree of join steps, each with two inputs. The planner examines different possible join sequences to find the cheapest one.

If the query uses fewer than \texttt{geqo\_threshold} relations, a near-exhaustive search is conducted to find the best join sequence. The planner preferentially considers joins between any two relations for which there exist a corresponding join clause in the \texttt{WHERE} qualification (i.e., for which a restriction like \texttt{where rel1.attr1=rel2.attr2} exists). Join pairs with no join clause are considered only when there is no other choice, that is, a particular relation has no available join clauses to any other relation. All possible plans are generated for every join pair considered by the planner, and the one that is (estimated to be) the cheapest is chosen.

When \texttt{geqo\_threshold} is exceeded, the join sequences considered are determined by heuristics, as described in Chapter 58. Otherwise the process is the same.

The finished plan tree consists of sequential or index scans of the base relations, plus nested-loop, merge, or hash join nodes as needed, plus any auxiliary steps needed, such as sort nodes or aggregate-function calculation nodes. Most of these plan node types have the additional ability to do \textit{selection} (discarding rows that do not meet a specified Boolean condition) and \textit{projection} (computation of a derived column set based on given column values, that is, evaluation of scalar expressions where needed). One of the responsibilities of the planner is to attach selection conditions from the \texttt{WHERE} clause and computation of required output expressions to the most appropriate nodes of the plan tree.

### 49.6. Executor

The \textit{executor} takes the plan created by the planner/optimizer and recursively processes it to extract the required set of rows. This is essentially a demand-pull pipeline mechanism. Each time a plan node is called, it must deliver one more row, or report that it is done delivering rows.

To provide a concrete example, assume that the top node is a \texttt{MergeJoin} node. Before any merge can be done two rows have to be fetched (one from each subplan). So the executor recursively calls itself to process the subplans (it starts with the subplan attached to \texttt{lettree}). The new top node (the top node of the left subplan) is, let’s say, a \texttt{Sort} node and again recursion is needed to obtain an input row. The child node of the \texttt{Sort} might be a \texttt{SeqScan} node, representing actual reading of a table. Execution of this node causes the executor to fetch a row from the table and return it up to the calling node. The \texttt{Sort} node will repeatedly call its child to obtain all the rows to be sorted. When the input is exhausted (as indicated by the child node returning a \texttt{NULL} instead of a row), the \texttt{Sort} code performs the sort, and finally is able to return its first output row, namely the first one in sorted order. It keeps the remaining rows stored so that it can deliver them in sorted order in response to later demands.

The \texttt{MergeJoin} node similarly demands the first row from its right subplan. Then it compares the two rows to see if they can be joined; if so, it returns a join row to its caller. On the next call, or immediately if it cannot join the current pair of inputs, it advances to the next row of one table or the other (depending on how the comparison came out), and again checks for a match. Eventually, one subplan or the other is exhausted, and the \texttt{MergeJoin} node returns \texttt{NULL} to indicate that no more join rows can be formed.

Complex queries can involve many levels of plan nodes, but the general approach is the same: each node computes and returns its next output row each time it is called. Each node is also responsible for applying any selection or projection expressions that were assigned to it by the planner.

The executor mechanism is used to evaluate all four basic SQL query types: \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE}. For \texttt{SELECT}, the top-level executor code only needs to send each row returned
by the query plan tree off to the client. For **INSERT**, each returned row is inserted into the target table specified for the **INSERT**. This is done in a special top-level plan node called **ModifyTable**. (A simple **INSERT ... VALUES** command creates a trivial plan tree consisting of a single **Result** node, which computes just one result row, and **ModifyTable** above it to perform the insertion. But **INSERT ... SELECT** can demand the full power of the executor mechanism.) For **UPDATE**, the planner arranges that each computed row includes all the updated column values, plus the **TID** (tuple ID, or row ID) of the original target row; this data is fed into a **ModifyTable** node, which uses the information to create a new updated row and mark the old row deleted. For **DELETE**, the only column that is actually returned by the plan is the **TID**, and the **ModifyTable** node simply uses the **TID** to visit each target row and mark it deleted.
Chapter 50. System Catalogs

The system catalogs are the place where a relational database management system stores schema metadata, such as information about tables and columns, and internal bookkeeping information. PostgreSQL’s system catalogs are regular tables. You can drop and recreate the tables, add columns, insert and update values, and severely mess up your system that way. Normally, one should not change the system catalogs by hand, there are normally SQL commands to do that. (For example, CREATE DATABASE inserts a row into the pg_database catalog — and actually creates the database on disk.) There are some exceptions for particularly esoteric operations, but many of those have been made available as SQL commands over time, and so the need for direct manipulation of the system catalogs is ever decreasing.

50.1. Overview

Table 50-1 lists the system catalogs. More detailed documentation of each catalog follows below.

Most system catalogs are copied from the template database during database creation and are thereafter database-specific. A few catalogs are physically shared across all databases in a cluster; these are noted in the descriptions of the individual catalogs.

Table 50-1. System Catalogs

<table>
<thead>
<tr>
<th>Catalog Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_aggregate</td>
<td>aggregate functions</td>

<td>mappings of users to foreign servers</td>
</tr>
</tbody>
</table>
50.2. pg_aggregate

The catalog pg_aggregate stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in pg_aggregate is an extension of an entry in pg_proc. The pg_proc entry carries the aggregate’s name, input and output data types, and other information that is similar to ordinary functions.

Table 50-2. pg_aggregate Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Approximate average size (in bytes) of the transition state data, or zero to use a default estimate</td>
</tr>
<tr>
<td>aggmtranstype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Data type of the aggregate function’s internal transition (state) data for moving-aggregate mode (zero if none)</td>
</tr>
<tr>
<td>aggmtransspace</td>
<td>int4</td>
<td></td>
<td>Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agginitval</td>
<td>text</td>
<td></td>
<td>The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.</td>
</tr>
<tr>
<td>aggminitval</td>
<td>text</td>
<td></td>
<td>The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is null, the transition state value starts out null.</td>
</tr>
</tbody>
</table>

New aggregate functions are registered with the CREATE AGGREGATE command. See Section 36.10 for more information about writing aggregate functions and the meaning of the transition functions, etc.

50.3. pg_am

The catalog pg_am stores information about relation access methods. There is one row for each access method supported by the system. Currently, only indexes have access methods. The requirements for index access methods are discussed in detail in Chapter 59.

Table 50-3. pg_am Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amname</td>
<td>name</td>
<td></td>
<td>Name of the access method</td>
</tr>
<tr>
<td>amhandler</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of a handler function that is responsible for supplying information about the access method</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amtype</td>
<td>char</td>
<td></td>
<td>Currently always i to indicate an index access method; other values may be allowed in future</td>
</tr>
</tbody>
</table>

Note: Before PostgreSQL 9.6, `pg_am` contained many additional columns representing properties of index access methods. That data is now only directly visible at the C code level. However, `pg_index_column_has_property()` and related functions have been added to allow SQL queries to inspect index access method properties; see Table 9-62.

50.4. pg_amop

The catalog `pg_amop` stores information about operators associated with access method operator families. There is one row for each operator that is a member of an operator family. A family member can be either a search operator or an ordering operator. An operator can appear in more than one family, but cannot appear in more than one search position nor more than one ordering position within a family. (It is allowed, though unlikely, for an operator to be used for both search and ordering purposes.)

Table 50-4. pg_amop Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amopfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amoplefttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of operator</td>
</tr>
<tr>
<td>amoprighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of operator</td>
</tr>
<tr>
<td>amopstrategy</td>
<td>int2</td>
<td></td>
<td>Operator strategy number</td>
</tr>
<tr>
<td>amoppurpose</td>
<td>char</td>
<td></td>
<td>Operator purpose, either s for search or o for ordering</td>
</tr>
<tr>
<td>amopopr</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>OID of the operator</td>
</tr>
<tr>
<td>amopmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>amopsortfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The B-tree operator family this entry sorts according to, if an ordering operator; zero if a search operator</td>
</tr>
</tbody>
</table>

1951
Chapter 50. System Catalogs

A “search” operator entry indicates that an index of this operator family can be searched to find all rows satisfying \( \text{WHERE indexed\_column operator constant} \). Obviously, such an operator must return boolean, and its left-hand input type must match the index’s column data type.

An “ordering” operator entry indicates that an index of this operator family can be scanned to return rows in the order represented by \( \text{ORDER BY indexed\_column operator constant} \). Such an operator could return any sortable data type, though again its left-hand input type must match the index’s column data type. The exact semantics of the \( \text{ORDER BY} \) are specified by the amopsortfamily column, which must reference a B-tree operator family for the operator’s result type.

**Note:** At present, it’s assumed that the sort order for an ordering operator is the default for the referenced operator family, i.e., ASC NULLS LAST. This might someday be relaxed by adding additional columns to specify sort options explicitly.

An entry’s amopmethod must match the opmethod of its containing operator family (including amopmethod here is an intentional denormalization of the catalog structure for performance reasons). Also, amoplefttype and amoprighttype must match the oprleft and oprright fields of the referenced pg_operator entry.

### 50.5. pg_amproc

The catalog pg_amproc stores information about support procedures associated with access method operator families. There is one row for each support procedure belonging to an operator family.

**Table 50-5. pg_amproc Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>amprocfamily</td>
<td>oid</td>
<td>pg_opfamily.oid</td>
<td>The operator family this entry is for</td>
</tr>
<tr>
<td>amproclefttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Left-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocrighttype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Right-hand input data type of associated operator</td>
</tr>
<tr>
<td>amprocnum</td>
<td>int2</td>
<td></td>
<td>Support procedure number</td>
</tr>
<tr>
<td>amproc</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the procedure</td>
</tr>
</tbody>
</table>

The usual interpretation of the amproclefttype and amprocrighttype fields is that they identify the left and right input types of the operator(s) that a particular support procedure supports. For some access methods these match the input data type(s) of the support procedure itself, for others not. There is a notion of “default” support procedures for an index, which are those with amproclefttype and amprocrighttype both equal to the index operator class’s opcintype.
50.6. pg_attrdef

The catalog pg_attrdef stores column default values. The main information about columns is stored in pg_attribute (see below). Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

Table 50-6. pg_attrdef Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>adrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>adnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the column</td>
</tr>
<tr>
<td>adbin</td>
<td>pg_node_tree</td>
<td></td>
<td>The internal representation of the column default value</td>
</tr>
<tr>
<td>adsrcc</td>
<td>text</td>
<td></td>
<td>A human-readable representation of the default value</td>
</tr>
</tbody>
</table>

The adsrcc field is historical, and is best not used, because it does not track outside changes that might affect the representation of the default value. Reverse-compiling the adbin field (with pg_get_expr for example) is a better way to display the default value.

50.7. pg_attribute

The catalog pg_attribute stores information about table columns. There will be exactly one pg_attribute row for every column in every table in the database. (There will also be attribute entries for indexes, and indeed all objects that have pg_class entries.)

The term attribute is equivalent to column and is used for historical reasons.

Table 50-7. pg_attribute Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this column belongs to</td>
</tr>
<tr>
<td>attname</td>
<td>name</td>
<td></td>
<td>The column name</td>
</tr>
<tr>
<td>atttypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The data type of this column</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>attstattarget</td>
<td>int4</td>
<td></td>
<td><strong>attstattarget</strong> controls the level of detail of statistics accumulated for this column by ANALYZE. A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, attstattarget is both the target number of “most common values” to collect, and the target number of histogram bins to create.</td>
</tr>
<tr>
<td>attlen</td>
<td>int2</td>
<td></td>
<td>A copy of pg_type.typlen of this column’s type</td>
</tr>
<tr>
<td>attnum</td>
<td>int2</td>

</tr>
<tr>
<td>attfdwoptions</td>
<td>text[]</td>
<td></td>
<td>Attribute-level foreign data wrapper options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

In a dropped column’s pg_attribute entry, atttypid is reset to zero, but attlen and the other fields copied from pg_type are still valid. This arrangement is needed to cope with the situation where the dropped column’s data type was later dropped, and so there is no pg_type row anymore. attlen and the other fields can be used to interpret the contents of a row of the table.

### 50.8. pg_authid

The catalog pg_authid contains information about database authorization identifiers (roles). A role subsumes the concepts of “users” and “groups”. A user is essentially just a role with the rolcanlogin flag set. Any role (with or without rolcanlogin) can have other roles as members; see pg_auth_members.

Since this catalog contains passwords, it must not be publicly readable. pg_roles is a publicly readable view on pg_authid that blanks out the password field.

Chapter 21 contains detailed information about user and privilege management.

Because user identities are cluster-wide, pg_authid is shared across all databases of a cluster: there is only one copy of pg_authid per cluster, not one per database.
<table>

</tr>
<tr>
<td>rolpword</td>
<td>text</td>
<td>Password (possibly encrypted); null if none. If the password is encrypted, this column will begin with the string md5 followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user’s password concatenated to their user name. For example, if user joe has password xyzzy, PostgreSQL will store the md5 hash of xyzzyjoe. A password that does not follow that format is assumed to be unencrypted.</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestamptz</td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
</tbody>
</table>
50.9. pg_auth_members

The catalog `pg_auth_members` shows the membership relations between roles. Any non-circular set of relationships is allowed.

Because user identities are cluster-wide, `pg_auth_members` is shared across all databases of a cluster: there is only one copy of `pg_auth_members` per cluster, not one per database.

<table>
<thead>

</tr>
<tr>
<td>admin_option</td>
<td>bool</td>
<td></td>
<td>True if <code>member</code> can grant membership in <code>roleid</code> to others</td>
</tr>
</tbody>
</table>

50.10. pg_cast

The catalog `pg_cast` stores data type conversion paths, both built-in and user-defined.

It should be noted that `pg_cast` does not represent every type conversion that the system knows how to perform; only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that “automatic I/O conversion casts”, those performed using a data type’s own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1958
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>castcontext</td>
<td>char</td>
<td></td>
<td>Indicates what contexts the cast can be invoked in. e means only as an explicit cast (using CAST or :: syntax), a means implicitly in assignment to a target column, as well as explicitly. i means implicitly in expressions, as well as the other cases.</td>
</tr>
<tr>
<td>castmethod</td>
<td>char</td>
<td></td>
<td>Indicates how the cast is performed. f means that the function specified in the castfunc field is used. i means that the input/output functions are used. b means that the types are binary-coercible, thus no conversion is required.</td>
</tr>
</tbody>
</table>

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or -1 if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent "length coercion functions" that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, it represents converting from one type to another and applying a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

#### 50.11. `pg_class`

The catalog `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table. This includes indexes (but see also `pg_index`), sequences, views, materialized views, composite types, and TOAST tables; see `relkind`. Below, when we mean all of these kinds of objects we speak of “relations”. Not all columns are meaningful for all relation types.

**Table 50-11. `pg_class` Columns**

</tr>
<tr>
<td>relispopulated</td>
<td>bool</td>
<td></td>
<td>True if relation is populated (this is true for all relations other than some materialized views).</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>relreplident</td>
<td>char</td>
<td></td>
<td>Columns used to form “replica identity” for rows: (d = \text{default}) (primary key, if any), (n = \text{nothing}), (f = \text{all}) columns (i = \text{index with indisreplident set, or default})</td>
</tr>
<tr>
<td>relfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow (\text{pg_clog}) to be shrunk. Zero ((\text{InvalidTransactionId})) if the relation is not a table.</td>
</tr>
<tr>
<td>relminmxid</td>
<td>xid</td>
<td></td>
<td>All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow (\text{pg_multixact}) to be shrunk. Zero ((\text{InvalidMultiXactId})) if the relation is not a table.</td>
</tr>
<tr>
<td>relacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see (\text{GRANT}) and (\text{REVOKE}) for details</td>
</tr>
<tr>
<td>reloptions</td>
<td>text[]</td>
<td></td>
<td>Access-method-specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

Several of the Boolean flags in \(\text{pg_class}\) are maintained lazily: they are guaranteed to be true if that’s the correct state, but may not be reset to false immediately when the condition is no longer true. For example, \(\text{relhasindex}\) is set by \(\text{CREATE INDEX}\), but it is never cleared by \(\text{DROP INDEX}\).
Instead, VACUUM clears relhasindex if it finds the table has no indexes. This arrangement avoids race conditions and improves concurrency.

50.12. pg_collation

The catalog pg_collation describes the available collations, which are essentially mappings from an SQL name to operating system locale categories. See Section 23.2 for more information.

Table 50-12. pg_collation Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>collname</td>
<td>name</td>
<td></td>
<td>Collation name (unique per namespace and encoding)</td>
</tr>
<tr>
<td>collnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this collation</td>
</tr>
<tr>
<td>collowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the collation</td>
</tr>
<tr>
<td>collencoding</td>
<td>int4</td>
<td></td>
<td>Encoding in which the collation is applicable, or -1 if it works for any encoding</td>
</tr>
<tr>
<td>collcollate</td>
<td>name</td>
<td></td>
<td>LC_COLLATE for this collation object</td>
</tr>
<tr>
<td>collctype</td>
<td>name</td>
<td></td>
<td>LC_CTYPE for this collation object</td>
</tr>
</tbody>
</table>

Note that the unique key on this catalog is (collname, collencoding, collnamespace) not just (collname, collnamespace). PostgreSQL generally ignores all collations that do not have collencoding equal to either the current database’s encoding or -1, and creation of new entries with the same name as an entry with collencoding = -1 is forbidden. Therefore it is sufficient to use a qualified SQL name (schema.name) to identify a collation, even though this is not unique according to the catalog definition. The reason for defining the catalog this way is that initdb fills it in at cluster initialization time with entries for all locales available on the system, so it must be able to hold entries for all encodings that might ever be used in the cluster.

In the template0 database, it could be useful to create collations whose encoding does not match the database encoding, since they could match the encodings of databases later cloned from template0. This would currently have to be done manually.

50.13. pg_constraint

The catalog pg_constraint stores check, primary key, unique, foreign key, and exclusion constraints on tables. (Column constraints are not treated specially. Every column constraint is equivalent to some table constraint.) Not-null constraints are represented in the pg_attribute catalog, not
User-defined constraint triggers (created with `CREATE CONSTRAINT TRIGGER`) also give rise to an entry in this table.

Check constraints on domains are stored here, too.

<p>| Name            | Type   | References        | Description                                                                 |
|-----------------|--------|-------------------|                                                                            |
| oid             | oid    |                   | Row identifier (hidden attribute; must be explicitly selected)             |
| conname         | name   |                   | Constraint name (not necessarily unique!)                                  |

<td></td>
<td>If a check constraint, a human-readable representation of the expression</td>
</tr>
</tbody>
</table>

In the case of an exclusion constraint, conkey is only useful for constraint elements that are simple column references. For other cases, a zero appears in conkey and the associated index must be consulted to discover the expression that is constrained. (conkey thus has the same contents as pg_index.indkey for the index.)

Note: consrc is not updated when referenced objects change; for example, it won’t track renaming of columns. Rather than relying on this field, it’s best to use pg_get_constraintdef() to extract the definition of a check constraint.

Note: pg_class.relchecks needs to agree with the number of check-constraint entries found in this table for each relation.

50.14. pg_conversion

The catalog pg_conversion describes encoding conversion procedures. See CREATE CONVERSION for more information.

</tbody>
</table>
### 50.15. `pg_database`

The catalog `pg_database` stores information about the available databases. Databases are created with the `CREATE DATABASE` command. Consult Chapter 22 for details about the meaning of some of the parameters.

Unlike most system catalogs, `pg_database` is shared across all databases of a cluster: there is only one copy of `pg_database` per cluster, not one per database.

**Table 50-15. `pg_database` Columns**

<table>
<thead>
<tr>

<td></td>
<td>Last system OID in the database; useful particularly to <code>pg_dump</code></td>
</tr>
<tr>
<td>datfrozenxid</td>
<td>xid</td>
<td></td>
<td>All transaction IDs before this one have been replaced with a permanent (“frozen”) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_clog</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relfrozenxid</code> values.</td>
</tr>
</tbody>
</table>
50.16. *pg_db_role_setting*

The catalog `pg_db_role_setting` records the default values that have been set for run-time configuration variables, for each role and database combination.

Unlike most system catalogs, `pg_db_role_setting` is shared across all databases of a cluster: there is only one copy of `pg_db_role_setting` per cluster, not one per database.

**Table 50-16. pg_db_role_setting Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setdatabase</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the setting is applicable to, or zero if not database-specific</td>
</tr>
</tbody>
</table>
50.17. **pg_default_acl**

The catalog *pg_default_acl* stores initial privileges to be assigned to newly created objects.

**Table 50-17. pg_default_acl Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>defaclrole</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>The OID of the role associated with this entry</td>
</tr>
<tr>
<td>defaclnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace associated with this entry, or 0 if none</td>
</tr>
<tr>
<td>defaclobjtype</td>
<td>char</td>
<td></td>
<td>Type of object this entry is for: r = relation (table, view), S = sequence, f = function, T = type</td>
</tr>
<tr>
<td>defaclacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges that this type of object should have on creation</td>
</tr>
</tbody>
</table>

A *pg_default_acl* entry shows the initial privileges to be assigned to an object belonging to the indicated user. There are currently two types of entry: “global” entries with `defaclnamespace = 0`, and “per-schema” entries that reference a particular schema. If a global entry is present then it overrides the normal hard-wired default privileges for the object type. A per-schema entry, if present, represents privileges to be added to the global or hard-wired default privileges.

Note that when an ACL entry in another catalog is null, it is taken to represent the hard-wired default privileges for its object, not whatever might be in *pg_default_acl* at the moment. *pg_default_acl* is only consulted during object creation.
50.18. pg_depend

The catalog pg_depend records the dependency relationships between database objects. This information allows DROP commands to find which other objects must be dropped by DROP CASCADE or prevent dropping in the DROP RESTRICT case.

See also pg_shdepend, which performs a similar function for dependencies involving objects that are shared across a database cluster.

Table 50-18. pg_depend Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>refobjsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the refobjid and refclassid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a pg_depend entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by deptype:

**DEPENDENCY_NORMAL (n)**

A normal relationship between separately-created objects. The dependent object can be dropped without affecting the referenced object. The referenced object can only be dropped by specifying CASCADE, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.
Chapter 50. System Catalogs

DEPENDENCY_AUTO (a)

The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of RESTRICT or CASCADE mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.

DEPENDENCY_INTERNAL (i)

The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A DROP of the dependent object will be disallowed outright (we’ll tell the user to issue a DROP against the referenced object, instead). A DROP of the referenced object will be propagated through to drop the dependent object whether CASCADE is specified or not. Example: a trigger that’s created to enforce a foreign-key constraint is made internally dependent on the constraint’s pg_constraint entry.

DEPENDENCY_EXTENSION (e)

The dependent object is a member of the extension that is the referenced object (see pg_extension). The dependent object can be dropped only via DROP EXTENSION on the referenced object. Functionally this dependency type acts the same as an internal dependency, but it’s kept separate for clarity and to simplify pg_dump.

DEPENDENCY_AUTO_EXTENSION (x)

The dependent object is not a member of the extension that is the referenced object (and so should not be ignored by pg_dump), but cannot function without it and should be dropped when the extension itself is. The dependent object may be dropped on its own as well.

DEPENDENCY_PIN (p)

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by initdb. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future.

50.19. pg_description

The catalog pg_description stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the COMMENT command and viewed with psql’s \d commands. Descriptions of many built-in system objects are provided in the initial contents of pg_description.

See also pg_shdescription, which performs a similar function for descriptions involving objects that are shared across a database cluster.

Table 50-19. pg_description Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
</tbody>
</table>
### 50.20. pg_enum

The `pg_enum` catalog contains entries showing the values and labels for each enum type. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>enumtypid</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>The OID of the <code>pg_type</code> entry owning this enum value</td>
</tr>
<tr>
<td>enumsortorder</td>
<td>float4</td>
<td></td>
<td>The sort position of this enum value within its enum type</td>
</tr>
<tr>
<td>enumlabel</td>
<td>name</td>
<td></td>
<td>The textual label for this enum value</td>
</tr>
</tbody>
</table>

The OIDs for `pg_enum` rows follow a special rule: even-numbered OIDs are guaranteed to be ordered in the same way as the sort ordering of their enum type. That is, if two even OIDs belong to the same enum type, the smaller OID must have the smaller `enumsortorder` value. Odd-numbered OID values need bear no relationship to the sort order. This rule allows the enum comparison routines to avoid catalog lookups in many common cases. The routines that create and alter enum types attempt to assign even OIDs to enum values whenever possible.

When an enum type is created, its members are assigned sort-order positions 1..n. But members added later might be given negative or fractional values of `enumsortorder`. The only requirement on these values is that they be correctly ordered and unique within each enum type.

### 50.21. pg_event_trigger

The catalog `pg_event_trigger` stores event triggers. See Chapter 38 for more information.
### Chapter 50. System Catalogs

#### Table 50-21. pg_event_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evtname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique)</td>
</tr>
<tr>
<td>evtevent</td>
<td>name</td>
<td></td>
<td>Identifies the event for which this trigger fires</td>
</tr>
<tr>
<td>evtowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the event trigger</td>
</tr>
<tr>
<td>evtfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>evtenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the event trigger fires. D = trigger disabled, R = trigger fires in “replica” mode, A = trigger fires always.</td>
</tr>
<tr>
<td>evttags</td>
<td>text[]</td>
<td></td>
<td>Command tags for which this trigger will fire. If NULL, the firing of this trigger is not restricted on the basis of the command tag.</td>
</tr>
</tbody>
</table>

#### 50.22. pg_extension

The catalog pg_extension stores information about the installed extensions. See Section 36.15 for details about extensions.

#### Table 50-22. pg_extension Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>extname</td>
<td>name</td>
<td></td>
<td>Name of the extension</td>
</tr>
<tr>
<td>extowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the extension</td>
</tr>
<tr>
<td>extnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Schema containing the extension’s exported objects</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extrelocatable</td>
<td>bool</td>
<td></td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>extversion</td>
<td>text</td>
<td></td>
<td>Version name for the extension</td>
</tr>
<tr>
<td>extconfig</td>
<td>oid[]</td>
<td>pg_class.oid</td>
<td>Array of regclass OIDs for the extension’s configuration table(s), or NULL if none</td>
</tr>
<tr>
<td>extcondition</td>
<td>text[]</td>
<td></td>
<td>Array of WHERE-clause filter conditions for the extension’s configuration table(s), or NULL if none</td>
</tr>
</tbody>
</table>

Note that unlike most catalogs with a “namespace” column, extnamespace is not meant to imply that the extension belongs to that schema. Extension names are never schema-qualified. Rather, extnamespace indicates the schema that contains most or all of the extension’s objects. If extrelocatable is true, then this schema must in fact contain all schema-qualifiable objects belonging to the extension.

50.23. pg_foreign_data_wrapper

The catalog pg_foreign_data_wrapper stores foreign-data wrapper definitions. A foreign-data wrapper is the mechanism by which external data, residing on foreign servers, is accessed.

Table 50-23. pg_foreign_data_wrapper Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>fdwname</td>
<td>name</td>
<td></td>
<td>Name of the foreign-data wrapper</td>
</tr>
<tr>
<td>fdwowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign-data wrapper</td>
</tr>
<tr>
<td>fdwhandler</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>References a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided</td>
</tr>
</tbody>
</table>
### 50.24. pg_foreign_server

The catalog `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. Foreign servers are accessed via foreign-data wrappers.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td></td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>srvowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the foreign server</td>
</tr>
<tr>
<td>srvfdw</td>
<td>oid</td>
<td>pg_foreign_data_wrapper.oid</td>
<td>OID of the foreign-data wrapper of this foreign server</td>
</tr>
<tr>
<td>srvtype</td>
<td>text</td>
<td></td>
<td>Type of the server (optional)</td>
</tr>
<tr>
<td>srvversion</td>
<td>text</td>
<td></td>
<td>Version of the server (optional)</td>
</tr>
<tr>
<td>srvacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>srvoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign server specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

#### 50.25. pg_foreign_table

The catalog `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

**Table 50-25. pg_foreign_table Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the <code>pg_class</code> entry for this foreign table</td>
</tr>
<tr>
<td>ftserver</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>OID of the foreign server for this foreign table</td>
</tr>
<tr>
<td>ftoptions</td>
<td>text[]</td>
<td></td>
<td>Foreign table options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

#### 50.26. pg_index

The catalog `pg_index` contains part of the information about indexes. The rest is mostly in `pg_class`.

**Table 50-26. pg_index Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the <code>pg_class</code> entry for this index</td>
</tr>
<tr>
<td>indrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the <code>pg_class</code> entry for the table this index is for</td>
</tr>
<tr>
<td>indnatts</td>
<td>int2</td>
<td></td>
<td>The number of columns in the index (duplicates <code>pg_class.relnatts</code>)</td>
</tr>
<tr>
<td>indisunique</td>
<td>bool</td>
<td></td>
<td>If true, this is a unique index</td>

<td>------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indisprimary</td>
<td>bool</td>
<td></td>
<td>If true, this index represents the primary key of the table (indisunique should always be true when this is true)</td>
</tr>
<tr>
<td>indisexclusion</td>
<td>bool</td>
<td></td>
<td>If true, this index supports an exclusion constraint</td>
</tr>
<tr>
<td>indimmediate</td>
<td>bool</td>
<td></td>
<td>If true, the uniqueness check is enforced immediately on insertion (irrelevant if indisunique is not true)</td>
</tr>
<tr>
<td>indisclustered</td>
<td>bool</td>
<td></td>
<td>If true, the table was last clustered on this index</td>
</tr>
<tr>
<td>indisvalid</td>
<td>bool</td>
<td></td>
<td>If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by INSERT/UPDATE operations, but it cannot safely be used for queries. If it is unique, the uniqueness property is not guaranteed true either.</td>
</tr>
<tr>
<td>indcheckxmin</td>
<td>bool</td>
<td></td>
<td>If true, queries must not use the index until the xmin of this pg_index row is below their TransactionXmin event horizon, because the table may contain broken HOT chains with incompatible rows that they can see</td>
</tr>
<tr>
<td>indisready</td>
<td>bool</td>
<td></td>
<td>If true, the index is currently ready for inserts. False means the index must be ignored by INSERT/UPDATE operations.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>indislive</td>
<td>bool</td>
<td></td>
<td>If false, the index is in process of being dropped, and should be ignored for all purposes (including HOT-safety decisions)</td>
</tr>
<tr>
<td>indisreplident</td>
<td>bool</td>
<td></td>
<td>If true this index has been chosen as “replica identity” using ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</td>
</tr>
<tr>
<td>indkey</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>This is an array of indnatts values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference.</td>
</tr>
<tr>
<td>indcollation</td>
<td>oidvector</td>
<td>pg_collation.oid</td>
<td>For each column in the index key, this contains the OID of the collation to use for the index.</td>
</tr>
<tr>
<td>indclass</td>
<td>oidvector</td>
<td>pg_opclass.oid</td>
<td>For each column in the index key, this contains the OID of the operator class to use. See pg_opclass for details.</td>
</tr>
<tr>
<td>indoption</td>
<td>int2vector</td>
<td></td>
<td>This is an array of indnatts values that store per-column flag bits. The meaning of the bits is defined by the index’s access method.</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

### Table 50-27. pg_inherits Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inhrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the child table</td>
</tr>
<tr>
<td>inhparent</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the parent table</td>
</tr>
<tr>
<td>inhseqno</td>
<td>int4</td>
<td></td>
<td>If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1.</td>
</tr>
</tbody>
</table>

50.27. **pg_inherits**

The catalog `pg_inherits` records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.)

50.28. **pg_init_privs**

The catalog `pg_init_privs` records information about the initial privileges of objects in the system. There is one entry for each object in the database which has a non-default (non-NULL) initial set of
privileges.

Objects can have initial privileges either by having those privileges set when the system is initialized (by initdb) or when the object is created during a CREATE Extension and the extension script sets initial privileges using the GRANT system. Note that the system will automatically handle recording of the privileges during the extension script and that extension authors need only use the GRANT and REVOKE statements in their script to have the privileges recorded. The privtype column indicates if the initial privilege was set by initdb or during a CREATE Extension command.

Objects which have initial privileges set by initdb will have entries where privtype is ‘i’, while objects which have initial privileges set by CREATE EXTENSION will have entries where privtype is ‘e’.

Table 50-28. pg_init_privs Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific object</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the object is in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>privtype</td>
<td>char</td>
<td></td>
<td>A code defining the type of initial privilege of this object; see text</td>
</tr>
<tr>
<td>initprivs</td>
<td>aclitem</td>
<td>[]</td>
<td>The initial access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

50.29. pg_language

The catalog pg_language registers languages in which you can write functions or stored procedures. See CREATE LANGUAGE and Chapter 40 for more information about language handlers.

Table 50-29. pg_language Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lanname</td>
<td>name</td>
<td></td>
<td>Name of the language</td>
</tr>
<tr>
<td>lanowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the language</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>lanispl</td>
<td>bool</td>
<td></td>
<td>This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this might be replaced by a different mechanism in the future.</td>
</tr>
<tr>
<td>lanpltrusted</td>
<td>bool</td>
<td></td>
<td>True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers can create functions in untrusted languages.</td>
</tr>
<tr>
<td>lanplcallfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>For noninternal languages this references the language handler, which is a special function that is responsible for executing all functions that are written in the particular language.</td>
</tr>
<tr>
<td>laninline</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a function that is responsible for executing “inline” anonymous code blocks (DO blocks). Zero if inline blocks are not supported.</td>
</tr>
<tr>
<td>lanvalidator</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.</td>
</tr>
</tbody>
</table>
50.30. **pg_largeobject**

The catalog `pg_largeobject` holds the data making up “large objects”. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or “pages” small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 2 kB).

Prior to PostgreSQL 9.0, there was no permission structure associated with large objects. As a result, `pg_largeobject` was publicly readable and could be used to obtain the OIDs (and contents) of all large objects in the system. This is no longer the case; use `pg_largeobject_metadata` to obtain a list of large object OIDs.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loid</td>
<td>oid</td>
<td><code>pg_largeobject_metadata</code>.oid</td>
<td>Identifier of the large object that includes this page</td>
</tr>
<tr>
<td>pageno</td>
<td>int4</td>
<td></td>
<td>Page number of this page within its large object (counting from zero)</td>
</tr>
<tr>
<td>data</td>
<td>bytea</td>
<td></td>
<td>Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and might be less.</td>
</tr>
</tbody>
</table>

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset `(pageno * LOBLKSIZE)` within the object. The implementation allows sparse storage: pages might be missing, and might be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

50.31. **pg_largeobject_metadata**

The catalog `pg_largeobject_metadata` holds metadata associated with large objects. The actual large object data is stored in `pg_largeobject`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lanacl</td>
<td>aclitem[]</td>
<td>References</td>
<td>Description</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>lomowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the large object</td>
</tr>
<tr>
<td>lomacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

50.32. pg_namespace

The catalog pg_namespace stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

Table 50-32. pg_namespace Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>nspname</td>
<td>name</td>
<td></td>
<td>Name of the namespace</td>
</tr>
<tr>
<td>nspowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the namespace</td>
</tr>
<tr>
<td>nspacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
</tbody>
</table>

50.33. pg_opclass

The catalog pg_opclass defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are whichever ones accept the column’s data type as their left-hand input.

Operator classes are described at length in Section 36.14.

Table 50-33. pg_opclass Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
</tbody>
</table>
### An operator class’s opcmethod must match the opfmethod of its containing operator family. Also, there must be no more than one pg_opclass row having opcdefault true for any given combination of opcmethod and opcintype.

#### 50.34. pg_operator

The catalog pg_operator stores information about operators. See CREATE OPERATOR and Section 36.12 for more information.

**Table 50-34. pg_operator Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>oprname</td>
<td>name</td>
<td></td>
<td>Name of the operator</td>
</tr>
<tr>
<td>oprnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this operator</td>
</tr>
<tr>
<td>oprowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator</td>
</tr>
<tr>
<td>oprkind</td>
<td>char</td>
<td></td>
<td>b = infix (“both”), l = prefix (“left”), r = postfix (“right”)</td>
</tr>
<tr>
<td>oprcanmerge</td>
<td>bool</td>
<td></td>
<td>This operator supports merge joins</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oprcanhash</td>
<td>bool</td>
<td></td>
<td>This operator supports hash joins</td>
</tr>
<tr>
<td>oprleft</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the left operand</td>
</tr>
<tr>
<td>oprright</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the right operand</td>
</tr>
<tr>
<td>oprresult</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Type of the result</td>
</tr>
<tr>
<td>oprcom</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Commutator of this operator, if any</td>
</tr>
<tr>
<td>oprnegate</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>Negator of this operator, if any</td>
</tr>
<tr>
<td>oprcode</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Function that implements this operator</td>
</tr>
<tr>
<td>oprrest</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Restriction selectivity estimation function for this operator</td>
</tr>
<tr>
<td>oprjoin</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Join selectivity estimation function for this operator</td>
</tr>
</tbody>
</table>

Unused column contain zeroes. For example, oprleft is zero for a prefix operator.

50.35. pg_opfamily

The catalog pg_opfamily defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all "compatible", in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

Operator families are described at length in Section 36.14.

Table 50-35. pg_opfamily Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>opfmethod</td>
<td>oid</td>
<td>pg_am.oid</td>
<td>Index access method operator family is for</td>
</tr>
<tr>
<td>opfname</td>
<td>name</td>
<td></td>
<td>Name of this operator family</td>
</tr>
<tr>
<td>opfnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>Namespace of this operator family</td>
</tr>
<tr>
<td>opfowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the operator family</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

50.36. pg_pltemplate

The catalog `pg_pltemplate` stores “template” information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details.

Unlike most system catalogs, `pg_pltemplate` is shared across all databases of a cluster: there is only one copy of `pg_pltemplate` per cluster, not one per database. This allows the information to be accessible in each database as it is needed.

Table 50-36. pg_pltemplate Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplname</td>
<td>name</td>
<td>Name of the language this template is for</td>
</tr>
<tr>
<td>tmpltrusted</td>
<td>boolean</td>
<td>True if language is considered trusted</td>
</tr>
<tr>
<td>tmpldbcreate</td>
<td>boolean</td>
<td>True if language may be created by a database owner</td>
</tr>
<tr>
<td>tmplhandler</td>
<td>text</td>
<td>Name of call handler function</td>
</tr>
<tr>
<td>tmplinline</td>
<td>text</td>
<td>Name of anonymous-block handler function, or null if none</td>
</tr>
<tr>
<td>tmplvalidator</td>
<td>text</td>
<td>Name of validator function, or null if none</td>
</tr>
<tr>
<td>tmppllibrary</td>
<td>text</td>
<td>Path of shared library that implements language</td>
</tr>
<tr>
<td>tmplacl</td>
<td>aclitem[]</td>
<td>Access privileges for template (not actually used)</td>
</tr>
</tbody>
</table>

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

Note: It is likely that `pg_pltemplate` will be removed in some future release of PostgreSQL, in favor of keeping this knowledge about procedural languages in their respective extension installation scripts.

50.37. pg_policy

The catalog `pg_policy` stores row level security policies for tables. A policy includes the kind of command that it applies to (possibly all commands), the roles that it applies to, the expression to be
added as a security-barrier qualification to queries that include the table, and the expression to be added as a WITH CHECK option for queries that attempt to add new records to the table.

Table 50-37. pg_policy Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>polname</td>
<td>name</td>
<td></td>
<td>The name of the policy</td>
</tr>
<tr>
<td>polrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table to which the policy applies</td>
</tr>
<tr>
<td>polcmd</td>
<td>char</td>
<td></td>
<td>The command type to which the policy is applied: r for SELECT, a for INSERT, w for UPDATE, d for DELETE, or * for all</td>
</tr>
<tr>
<td>polroles</td>
<td>oid[]</td>
<td>pg_authid.oid</td>
<td>The roles to which the policy is applied</td>
</tr>
<tr>
<td>polqual</td>
<td>pg_node_tree</td>
<td></td>
<td>The expression tree to be added to the security barrier qualifications for queries that use the table</td>
</tr>
<tr>
<td>polwithcheck</td>
<td>pg_node_tree</td>
<td></td>
<td>The expression tree to be added to the WITH CHECK qualifications for queries that attempt to add rows to the table</td>
</tr>
</tbody>
</table>

**Note:** Policies stored in pg_policy are applied only when pg_class.relrowsecurity is set for their table.

50.38. pg_proc

The catalog pg_proc stores information about functions (or procedures). See CREATE FUNCTION and Section 36.3 for more information.

The table contains data for aggregate functions as well as plain functions. If proisagg is true, there should be a matching row in pg_aggregate.

Table 50-38. pg_proc Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>prówname</td>
<td>name</td>
<td></td>
<td>Name of the function</td>
</tr>
</tbody>
</table>

<td>Function is a window function</td>
</tr>
<tr>
<td>prosecdef</td>
<td>bool</td>
<td></td>
<td>Function is a security definer (i.e., a “setuid” function)</td>
</tr>
<tr>
<td>proleakproof</td>
<td>bool</td>
<td></td>
<td>The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.</td>
</tr>
</tbody>
</table>
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proisstrict</td>
<td>bool</td>
<td></td>
<td>Function returns null if any call argument is null. In that case the function won’t actually be called at all. Functions that are not “strict” must be prepared to handle null inputs.</td>
</tr>
<tr>
<td>proretset</td>
<td>bool</td>
<td></td>
<td>Function returns a set (i.e., multiple values of the specified data type)</td>
</tr>
<tr>
<td>provolatile</td>
<td>char</td>
<td></td>
<td>provolatile tells whether the function’s result depends only on its input arguments, or is affected by outside factors. It is i for “immutable” functions, which always deliver the same result for the same inputs. It is s for “stable” functions, whose results (for fixed inputs) do not change within a scan. It is v for “volatile” functions, whose results might change at any time. (Use v also for functions with side-effects, so that calls to them cannot get optimized away.)</td>
</tr>
</tbody>
</table>
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proparallel</td>
<td>char</td>
<td></td>
<td>proparallel tells whether the function can be safely run in parallel mode. It is s for functions which are safe to run in parallel mode without restriction. It is r for functions which can be run in parallel mode, but their execution is restricted to the parallel group leader; parallel worker processes cannot invoke these functions. It is u for functions which are unsafe in parallel mode; the presence of such a function forces a serial execution plan.</td>
</tr>
<tr>
<td>pronargs</td>
<td>int2</td>
<td></td>
<td>Number of input arguments</td>
</tr>
<tr>
<td>pronargdefaults</td>
<td>int2</td>
<td></td>
<td>Number of arguments that have defaults</td>

<tr>
<td>prorettype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>Data type of the return value</td>
</tr>
<tr>
<td>proargtypes</td>
<td>oidvector</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes only input arguments (including INOUT and VARIADIC arguments), and thus represents the call signature of the function.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>proallargtypes</td>
<td>oid[]</td>
<td>pg_type.oid</td>
<td>An array with the data types of the function arguments. This includes all arguments (including OUT and INOUT arguments); however, if all the arguments are IN arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons proargtypes is subscripted from 0.</td>
</tr>
<tr>
<td>proargmodes</td>
<td>char[]</td>
<td></td>
<td>An array with the modes of the function arguments, encoded as i for IN arguments, o for OUT arguments, b for INOUT arguments, v for VARIADIC arguments, t for TABLE arguments. If all the arguments are IN arguments, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>proargnames</td>
<td>text[]</td>
<td></td>
<td>An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of proallargtypes not proargtypes.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>proargdefaults</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression trees (in nodeToString() representation) for default values. This is a list with pronargdefaults elements, corresponding to the last ( N ) input arguments (i.e., the last ( N ) proargtypes positions). If none of the arguments have defaults, this field will be null.</td>
</tr>
<tr>
<td>protrftypes</td>
<td>oid[]</td>
<td></td>
<td>Data type OIDs for which to apply transforms.</td>
</tr>
<tr>
<td>prosrc</td>
<td>text</td>
<td></td>
<td>This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.</td>
</tr>
<tr>
<td>probin</td>
<td>text</td>
<td></td>
<td>Additional information about how to invoke the function. Again, the interpretation is language-specific.</td>
</tr>
<tr>
<td>proconfig</td>
<td>text[]</td>
<td></td>
<td>Function’s local settings for run-time configuration variables</td>
</tr>
<tr>
<td>proacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details.</td>
</tr>
</tbody>
</table>

For compiled functions, both built-in and dynamically loaded, prosrc contains the function’s C-language name (link symbol). For all other currently-known language types, prosrc contains the function’s source text. probin is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.
### 50.39. *pg_range*

The catalog `pg_range` stores information about range types. This is in addition to the types’ entries in `pg_type`.

**Table 50-39. `pg_range` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rngtypid</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>OID of the range type</td>
</tr>
<tr>
<td>rngsubtype</td>
<td>oid</td>
<td><code>pg_type.oid</code></td>
<td>OID of the element type (subtype) of this range type</td>
</tr>
<tr>
<td>rngcollation</td>
<td>oid</td>
<td><code>pg_collation.oid</code></td>
<td>OID of the collation used for range comparisons, or 0 if none</td>
</tr>
<tr>
<td>rngsubopc</td>
<td>oid</td>
<td><code>pg_opclass.oid</code></td>
<td>OID of the subtype’s operator class used for range comparisons</td>
</tr>
<tr>
<td>rngcanonical</td>
<td>regproc</td>
<td><code>pg_proc.oid</code></td>
<td>OID of the function to convert a range value into canonical form, or 0 if none</td>
</tr>
<tr>
<td>rngsubdiff</td>
<td>regproc</td>
<td><code>pg_proc.oid</code></td>
<td>OID of the function to return the difference between two element values as double precision, or 0 if none</td>
</tr>
</tbody>
</table>

`rngsubopc` (plus `rngcollation`, if the element type is collatable) determines the sort ordering used by the range type. `rngcanonical` is used when the element type is discrete. `rngsubdiff` is optional but should be supplied to improve performance of GiST indexes on the range type.

### 50.40. *pg_replication_origin*

The `pg_replication_origin` catalog contains all replication origins created. For more on replication origins see Chapter 48.

**Table 50-40. `pg_replication_origin` Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>
| roident | Oid  |            | A unique, cluster-wide identifier for the replication origin. Should never leave the system.
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roname</td>
<td>text</td>
<td></td>
<td>The external, user defined, name of a replication origin.</td>
</tr>
</tbody>
</table>

50.41. *pg_rewrite*

The catalog *pg_rewrite* stores rewrite rules for tables and views.

**Table 50-41. *pg_rewrite* Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td></td>
<td>Rule name</td>
</tr>
<tr>
<td>ev_class</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this rule is for</td>
</tr>
<tr>
<td>ev_type</td>
<td>char</td>
<td></td>
<td>Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE</td>
</tr>
<tr>
<td>ev_enabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the rule fires. O = rule fires in “origin” and “local” modes, D = rule is disabled, R = rule fires in “replica” mode, A = rule fires always.</td>
</tr>
<tr>
<td>is_instead</td>
<td>bool</td>
<td></td>
<td>True if the rule is an INSTEAD rule</td>
</tr>
<tr>
<td>ev_qual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in the form of a nodeToString() representation) for the rule’s qualifying condition</td>
</tr>
<tr>
<td>ev_action</td>
<td>pg_node_tree</td>
<td></td>
<td>Query tree (in the form of a nodeToString() representation) for the rule’s action</td>
</tr>
</tbody>
</table>

*Note:* *pg_class.relhasrules* must be true if a table has any rules in this catalog.
50.42. *pg_seclabel*

The catalog *pg_seclabel* stores security labels on database objects. Security labels can be manipulated with the SECURITY LABEL command. For an easier way to view security labels, see Section 50.74.

See also *pg_shseclabel*, which performs a similar function for security labels of database objects that are shared across a database cluster.

**Table 50-42. pg_seclabel Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number (the objoid and classoid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
<tr>
<td>label</td>
<td>text</td>
<td></td>
<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

50.43. *pg_shdepend*

The catalog *pg_shdepend* records the dependency relationships between database objects and shared objects, such as roles. This information allows PostgreSQL to ensure that those objects are unreferenced before attempting to delete them.

See also *pg_depend*, which performs a similar function for dependencies involving objects within a single database.

Unlike most system catalogs, *pg_shdepend* is shared across all databases of a cluster: there is only one copy of *pg_shdepend* per cluster, not one per database.

**Table 50-43. pg_shdepend Columns**

| Name   | Type     | References | Description |
|--------|----------|------------|-------------|-------------|

1997
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbid</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>The OID of the database the dependent object is in, or zero for a shared object</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the dependent object is in</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific dependent object</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a table column, this is the column number (the objid and classid refer to the table itself). For all other object types, this column is zero.</td>
</tr>
<tr>
<td>refclassid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog the referenced object is in (must be a shared catalog)</td>
</tr>
<tr>
<td>refobjid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the specific referenced object</td>
</tr>
<tr>
<td>deptype</td>
<td>char</td>
<td></td>
<td>A code defining the specific semantics of this dependency relationship; see text</td>
</tr>
</tbody>
</table>

In all cases, a `pg_shdepend` entry indicates that the referenced object cannot be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

**SHARED_DEPENDENCY_OWNER (o)**

The referenced object (which must be a role) is the owner of the dependent object.

**SHARED_DEPENDENCY_ACL (a)**

The referenced object (which must be a role) is mentioned in the ACL (access control list, i.e., privileges list) of the dependent object. (A `SHARED_DEPENDENCY_ACL` entry is not made for the owner of the object, since the owner will have a `SHARED_DEPENDENCY_OWNER` entry anyway.)

**SHARED_DEPENDENCY_POLICY (r)**

The referenced object (which must be a role) is mentioned as the target of a dependent policy object.

**SHARED_DEPENDENCY_PIN (p)**

There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by `initdb`. The columns for the dependent object contain zeroes.

Other dependency flavors might be needed in future. Note in particular that the current definition only supports roles as referenced objects.
50.44. pg_shdescription

The catalog `pg_shdescription` stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the \texttt{COMMENT} command and viewed with \texttt{psql}'s \texttt{\textbackslash d} commands.

See also `pg_description`, which performs a similar function for descriptions involving objects within a single database.

Unlike most system catalogs, `pg_shdescription` is shared across all databases of a cluster: there is only one copy of `pg_shdescription` per cluster, not one per database.

Table 50-44. pg_shdescription Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this description pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>\texttt{pg_class.oid}</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>description</td>
<td>text</td>
<td></td>
<td>Arbitrary text that serves as the description of this object</td>
</tr>
</tbody>
</table>

50.45. pg_shseclabel

The catalog `pg_shseclabel` stores security labels on shared database objects. Security labels can be manipulated with the \texttt{SECURITY LABEL} command. For an easier way to view security labels, see Section 50.74.

See also `pg_seclabel`, which performs a similar function for security labels involving objects within a single database.

Unlike most system catalogs, `pg_shseclabel` is shared across all databases of a cluster: there is only one copy of `pg_shseclabel` per cluster, not one per database.

Table 50-45. pg_shseclabel Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>\texttt{pg_class.oid}</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>provider</td>
<td>text</td>
<td></td>
<td>The label provider associated with this label.</td>
</tr>
</tbody>
</table>
50.46. pg_statistic

The catalog pg_statistic stores statistical data about the contents of the database. Entries are created by ANALYZE and subsequently used by the query planner. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

Normally there is one entry, with stainherit = false, for each table column that has been analyzed. If the table has inheritance children, a second entry with stainherit = true is also created. This row represents the column’s statistics over the inheritance tree, i.e., statistics for the data you’d see with SELECT column FROM table*, whereas the stainherit = false row represents the results of SELECT column FROM ONLY table.

pg_statistic also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, starelid references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have stainherit = false.

Since different kinds of statistics might be appropriate for different kinds of data, pg_statistic is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in pg_statistic. Everything else is stored in “slots”, which are groups of associated columns whose content is identified by a code number in one of the slot’s columns. For more information see src/include/catalog/pg_statistic.h.

pg_statistic should not be readable by the public, since even statistical information about a table’s contents might be considered sensitive. (Example: minimum and maximum values of a salary column might be quite interesting.) pg_stats is a publicly readable view on pg_statistic that only exposes information about those tables that are readable by the current user.

Table 50-46. pg_statistic Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>starelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table or index that the described column belongs to</td>
</tr>
<tr>
<td>staattnum</td>
<td>int2</td>
<td>pg_attribute.attnum</td>
<td>The number of the described column</td>
</tr>
<tr>
<td>stainherit</td>
<td>bool</td>
<td></td>
<td>If true, the stats include inheritance child columns, not just the values in the specified relation</td>
</tr>
<tr>
<td>stanullfrac</td>
<td>float4</td>
<td></td>
<td>The fraction of the column’s entries that are null</td>
</tr>
</tbody>
</table>
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stawidth</td>
<td>int4</td>
<td></td>
<td>The average stored width, in bytes, of nonnull entries</td>
</tr>
<tr>
<td>stadistinct</td>
<td>float4</td>
<td></td>
<td>The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a multiplier for the number of rows in the table; for example, a column in which about 80% of the values are nonnull and each nonnull value appears about twice on average could be represented by stadistinct = -0.4. A zero value means the number of distinct values is unknown.</td>
</tr>
<tr>
<td>stakindN</td>
<td>int2</td>
<td></td>
<td>A code number indicating the kind of statistics stored in the Nth “slot” of the pg_statistic row.</td>
</tr>
<tr>
<td>staopN</td>
<td>oid</td>
<td>pg_operator.oid</td>
<td>An operator used to derive the statistics stored in the Nth “slot”. For example, a histogram slot would show the &lt; operator that defines the sort order of the data.</td>
</tr>
<tr>
<td>stanumbersN</td>
<td>float4[]</td>
<td></td>
<td>Numerical statistics of the appropriate kind for the Nth “slot”, or null if the slot kind does not involve numerical values</td>
</tr>
</tbody>
</table>
50.47. pg_tablespace

The catalog `pg_tablespace` stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout.

Unlike most system catalogs, `pg_tablespace` is shared across all databases of a cluster: there is only one copy of `pg_tablespace` per cluster, not one per database.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>spcname</td>
<td>name</td>
<td></td>
<td>Tablespace name</td>
</tr>
<tr>
<td>spcowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the tablespace, usually the user who created it</td>
</tr>
<tr>
<td>spcacl</td>
<td>aclitem[]</td>
<td></td>
<td>Access privileges; see GRANT and REVOKE for details</td>
</tr>
<tr>
<td>spcoptions</td>
<td>text[]</td>
<td></td>
<td>Tablespace-level options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

50.48. pg_transform

The catalog `pg_transform` stores information about transforms, which are a mechanism to adapt data types to procedural languages. See CREATE TRANSFORM for more information.
Table 50-48. pg_transform Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trftype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>OID of the data type this transform is for</td>
</tr>
<tr>
<td>trflang</td>
<td>oid</td>
<td>pg_language.oid</td>
<td>OID of the language this transform is for</td>
</tr>
<tr>
<td>trffromsql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting the data type for input to the procedural language (e.g., function parameters). Zero is stored if this operation is not supported.</td>
</tr>
<tr>
<td>trftosql</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>The OID of the function to use when converting output from the procedural language (e.g., return values) to the data type. Zero is stored if this operation is not supported.</td>
</tr>
</tbody>
</table>

50.49. pg_trigger

The catalog pg_trigger stores triggers on tables and views. See CREATE TRIGGER for more information.

Table 50-49. pg_trigger Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>tgrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table this trigger is on</td>
</tr>
<tr>
<td>tgnname</td>
<td>name</td>
<td></td>
<td>Trigger name (must be unique among triggers of same table)</td>
</tr>
<tr>
<td>tgfoid</td>
<td>oid</td>
<td>pg_proc.oid</td>
<td>The function to be called</td>
</tr>
<tr>
<td>tgttype</td>
<td>int2</td>
<td></td>
<td>Bit mask identifying trigger firing conditions</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>----------</td>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>tgenabled</td>
<td>char</td>
<td></td>
<td>Controls in which session_replication_role modes the trigger fires. <strong>O</strong> = trigger fires in “origin” and “local” modes, <strong>D</strong> = trigger is disabled, <strong>R</strong> = trigger fires in “replica” mode, <strong>A</strong> = trigger fires always.</td>
</tr>
<tr>
<td>tgisinternal</td>
<td>bool</td>
<td></td>
<td>True if trigger is internally generated (usually, to enforce the constraint identified by tgressinternal)</td>
</tr>
<tr>
<td>tgconstrrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The table referenced by a referential integrity constraint</td>
</tr>
<tr>
<td>tgconstrindid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The index supporting a unique, primary key, referential integrity, or exclusion constraint</td>
</tr>
<tr>
<td>tgconstraint</td>
<td>oid</td>
<td>pg_constraint.oid</td>
<td>The pg_constraint entry associated with the trigger, if any</td>
</tr>
<tr>
<td>tgdeferrable</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is deferrable</td>
</tr>
<tr>
<td>tginitdeferred</td>
<td>bool</td>
<td></td>
<td>True if constraint trigger is initially deferred</td>
</tr>
<tr>
<td>tgnargs</td>
<td>int2</td>
<td></td>
<td>Number of argument strings passed to trigger function</td>
</tr>
<tr>
<td>tgattr</td>
<td>int2vector</td>
<td>pg_attribute.attnum</td>
<td>Column numbers, if trigger is column-specific; otherwise an empty array</td>
</tr>
<tr>
<td>tgargs</td>
<td>bytea</td>
<td></td>
<td>Argument strings to pass to trigger, each NULL-terminated</td>
</tr>
<tr>
<td>tgqual</td>
<td>pg_node_tree</td>
<td></td>
<td>Expression tree (in nodelistToString() representation) for the trigger’s WHEN condition, or null if none</td>
</tr>
</tbody>
</table>
Currently, column-specific triggering is supported only for `UPDATE` events, and so `tgattr` is relevant only for that event type. `tgtype` might contain bits for other event types as well, but those are presumed to be table-wide regardless of what is in `tgattr`.

**Note:** When `tgconstraint` is nonzero, `tgconstrrelid`, `tgconstrindid`, `tgdeferrable`, and `tginitdeferred` are largely redundant with the referenced `pg_constraint` entry. However, it is possible for a non-deferrable trigger to be associated with a deferrable constraint: foreign key constraints can have some deferrable and some non-deferrable triggers.

**Note:** `pg_class.relhastriggers` must be true if a relation has any triggers in this catalog.

### 50.50. pg_ts_config

The `pg_ts_config` catalog contains entries representing text search configurations. A configuration specifies a particular text search parser and a list of dictionaries to use for each of the parser’s output token types. The parser is shown in the `pg_ts_config` entry, but the token-to-dictionary mapping is defined by subsidiary entries in `pg_ts_config_map`. PostgreSQL’s text search features are described at length in Chapter 12.

**Table 50-50. pg_ts_config Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>cfgname</td>
<td>name</td>
<td></td>
<td>Text search configuration name</td>
</tr>
<tr>
<td>cfgnamespace</td>
<td>oid</td>
<td><code>pg_namespace.oid</code></td>
<td>The OID of the namespace that contains this configuration</td>
</tr>
<tr>
<td>cfgowner</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>Owner of the configuration</td>
</tr>
<tr>
<td>cfgparser</td>
<td>oid</td>
<td><code>pg_ts_parser.oid</code></td>
<td>The OID of the text search parser for this configuration</td>
</tr>
</tbody>
</table>

### 50.51. pg_ts_config_map

The `pg_ts_config_map` catalog contains entries showing which text search dictionaries should be consulted, and in what order, for each output token type of each text search configuration’s parser. PostgreSQL’s text search features are described at length in Chapter 12.
Table 50-51. pg_ts_config_map Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapcfg</td>
<td>oid</td>
<td>pg_ts_config.oid</td>
<td>The OID of the pg_ts_config entry owning this map entry</td>
</tr>
<tr>
<td>maptokentype</td>
<td>integer</td>
<td></td>
<td>A token type emitted by the configuration’s parser</td>
</tr>
<tr>
<td>mapseqno</td>
<td>integer</td>
<td></td>
<td>Order in which to consult this entry (lower mapseqnos first)</td>
</tr>
<tr>
<td>mapdict</td>
<td>oid</td>
<td>pg_ts_dict.oid</td>
<td>The OID of the text search dictionary to consult</td>
</tr>
</tbody>
</table>

50.52. pg_ts_dict

The pg_ts_dict catalog contains entries defining text search dictionaries. A dictionary depends on a text search template, which specifies all the implementation functions needed; the dictionary itself provides values for the user-settable parameters supported by the template. This division of labor allows dictionaries to be created by unprivileged users. The parameters are specified by a text string dictinitoption, whose format and meaning vary depending on the template.

PostgreSQL’s text search features are described at length in Chapter 12.

Table 50-52. pg_ts_dict Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>dictname</td>
<td>name</td>
<td></td>
<td>Text search dictionary name</td>
</tr>
<tr>
<td>dictnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this dictionary</td>
</tr>
<tr>
<td>dictowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the dictionary</td>
</tr>
<tr>
<td>dicttemplate</td>
<td>oid</td>
<td>pg_ts_template.oid</td>
<td>The OID of the text search template for this dictionary</td>
</tr>
<tr>
<td>dictinitoption</td>
<td>text</td>
<td></td>
<td>Initialization option string for the template</td>
</tr>
</tbody>
</table>
50.53. **pg_ts_parser**

The `pg_ts_parser` catalog contains entries defining text search parsers. A parser is responsible for splitting input text into lexemes and assigning a token type to each lexeme. Since a parser must be implemented by C-language-level functions, creation of new parsers is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>prsname</td>
<td>name</td>
<td></td>
<td>Text search parser name</td>
</tr>
<tr>
<td>prsnnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this parser</td>
</tr>
<tr>
<td>prsstart</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s startup function</td>
</tr>
<tr>
<td>prstoken</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s next-token function</td>
</tr>
<tr>
<td>prsend</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s shutdown function</td>
</tr>
<tr>
<td>prsheadline</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s headline function</td>
</tr>
<tr>
<td>prslextype</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the parser’s lexttype function</td>
</tr>
</tbody>
</table>

50.54. **pg_ts_template**

The `pg_ts_template` catalog contains entries defining text search templates. A template is the implementation skeleton for a class of text search dictionaries. Since a template must be implemented by C-language-level functions, creation of new templates is restricted to database superusers.

PostgreSQL’s text search features are described at length in Chapter 12.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>tmplname</td>
<td>name</td>
<td></td>
<td>Text search template name</td>
</tr>
<tr>
<td>tmplnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this template</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmplinit</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the template’s initialization function</td>
</tr>
<tr>
<td>tmpllexize</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>OID of the template’s lexize function</td>
</tr>
</tbody>
</table>

50.55. pg_type

The catalog pg_type stores information about data types. Base types and enum types (scalar types) are created with CREATE TYPE, and domains with CREATE DOMAIN. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with CREATE TYPE AS.

Table 50-55. pg_type Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid</td>
<td>oid</td>
<td></td>
<td>Row identifier (hidden attribute; must be explicitly selected)</td>
</tr>
<tr>
<td>typname</td>
<td>name</td>
<td></td>
<td>Data type name</td>
</tr>
<tr>
<td>typnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace that contains this type</td>
</tr>
<tr>
<td>typowner</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>Owner of the type</td>
</tr>
<tr>
<td>typlen</td>
<td>int2</td>
<td></td>
<td>For a fixed-size type, typlen is the number of bytes in the internal representation of the type. But for a variable-length type, typlen is negative. -1 indicates a “varlena” type (one that has a length word), -2 indicates a null-terminated C string.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>typbyval</td>
<td>bool</td>
<td></td>
<td>typbyval determines whether internal routines pass a value of this type by value or by reference. typbyval had better be false if typlen is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that typbyval can be false even if the length would allow pass-by-value.</td>
</tr>
<tr>
<td>typtype</td>
<td>char</td>
<td></td>
<td>typtype is b for a base type, c for a composite type (e.g., a table’s row type), d for a domain, e for an enum type, p for a pseudo-type, or r for a range type. See also typrelid and typbasetype.</td>
</tr>
<tr>
<td>typcategory</td>
<td>char</td>
<td></td>
<td>typcategory is an arbitrary classification of data types that is used by the parser to determine which implicit casts should be “preferred”. See Table 50-56.</td>
</tr>
<tr>
<td>typispreferred</td>
<td>bool</td>
<td></td>
<td>True if the type is a preferred cast target within its typcategory</td>
</tr>
<tr>
<td>typisdefined</td>
<td>bool</td>
<td></td>
<td>True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When typisdefined is false, nothing except the type name, namespace, and OID can be relied on.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>typdelim</td>
<td>char</td>
<td></td>
<td>Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.</td>
</tr>
<tr>
<td>typrelid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>If this is a composite type (see typtype), then this column points to the pg_class entry that defines the corresponding table. (For a free-standing composite type, the pg_class entry doesn’t really represent a table, but it is needed anyway for the type’s pg_attribute entries to link to.) Zero for non-composite types.</td>
</tr>
</tbody>
</table>
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typelem</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>If <code>typelem</code> is not 0 then it identifies another row in <code>pg_type</code>. The current type can then be subscripted like an array yielding values of type <code>typelem</code>. A “true” array type is variable length (<code>typlen = -1</code>), but some fixed-length (<code>typlen &gt; 0</code>) types also have nonzero <code>typelem</code>, for example <code>name</code> and <code>point</code>. If a fixed-length type has a <code>typelem</code> then its internal representation must be some number of values of the <code>typelem</code> data type with no other data. Variable-length array types have a header defined by the array subroutines.</td>
</tr>
<tr>
<td>typarray</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>If <code>typarray</code> is not 0 then it identifies another row in <code>pg_type</code>, which is the “true” array type having this type as element</td>
</tr>
<tr>

<td>regproc</td>
<td>pg_proc.oid</td>
<td>Type modifier output function, or 0 to use the standard format</td>
</tr>
<tr>
<td>typanalyze</td>
<td>regproc</td>
<td>pg_proc.oid</td>
<td>Custom <code>ANALYZE</code> function, or 0 to use the standard function</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>typalign</td>
<td>char</td>
<td></td>
<td>typalign is the alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside PostgreSQL. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are: • c = char alignment, i.e., no alignment needed. • s = short alignment (2 bytes on most machines). • i = int alignment (4 bytes on most machines). • d = double alignment (8 bytes on many machines, but by no means all).</td>
</tr>
</tbody>
</table>

**Note:** For types used in system tables, it is critical that the size and alignment defined in `pg_type` agree with the way that the compiler will lay out the column in a structure representing a table row.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typstorage</td>
<td>char</td>
<td></td>
<td>typstorage tells for varlena types (those with <code>typlen = -1</code>) if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are: • p: Value must always be stored plain. • e: Value can be stored in a &quot;secondary&quot; relation (if relation has one, see <code>pg_class.reltoastrelid</code>). • m: Value can be stored compressed inline. • x: Value can be stored compressed inline or stored in &quot;secondary&quot; storage. Note that m columns can also be moved out to secondary storage, but only as a last resort (e and x columns are moved first).</td>
</tr>
<tr>
<td>typnotnull</td>
<td>bool</td>
<td></td>
<td>typnotnull represents a not-null constraint on a type. Used for domains only.</td>
</tr>
<tr>
<td>typbasetype</td>
<td>oid</td>
<td>pg_type.oid</td>
<td>If this is a domain (see <code>typtype</code>), then <code>typbasetype</code> identifies the type that this one is based on. Zero if this type is not a domain.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>--------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>typtypmod</td>
<td>int4</td>
<td></td>
<td>Domains use typtypmod to record the typmod to be applied to their base type (-1 if base type does not use a typmod). -1 if this type is not a domain.</td>
</tr>
<tr>
<td>typndims</td>
<td>int4</td>
<td></td>
<td>typndims is the number of array dimensions for a domain over an array (that is, typbasetype is an array type). Zero for types other than domains over array types.</td>
</tr>
<tr>
<td>typcollation</td>
<td>oid</td>
<td>pg_collation oid</td>
<td>typcollation specifies the collation of the type. If the type does not support collations, this will be zero. A base type that supports collations will have DEFAULT_COLLATION_OID here. A domain over a collatable type can have some other collation OID, if one was specified for the domain.</td>
</tr>
<tr>
<td>typdefaultbin</td>
<td>pg_node_tree</td>
<td></td>
<td>If typdefaultbin is not null, it is the nodeToString() representation of a default expression for the type. This is only used for domains.</td>
</tr>
<tr>

</tbody>
</table>

50.57. System Views

In addition to the system catalogs, PostgreSQL provides a number of built-in views. Some system views provide convenient access to some commonly used queries on the system catalogs. Other views provide access to internal server state.

The information schema (Chapter 35) provides an alternative set of views which overlap the functionality of the system views. Since the information schema is SQL-standard whereas the views described here are PostgreSQL-specific, it’s usually better to use the information schema if it provides all the information you need.

Table 50-58 lists the system views described here. More detailed documentation of each view follows below. There are some additional views that provide access to the results of the statistics collector; they are described in Table 28-2.

Except where noted, all the views described here are read-only.

**Table 50-58. System Views**

### View Name | Purpose
--- | ---
pg_locks | locks currently held or awaited
pg_matviews | materialized views
pg_policies | policies
pg_prepared_statements | prepared statements
pg_prepared_xacts | prepared transactions
pg_replication_origin_status | information about replication origins, including replication progress
pg_replication_slots | replication slot information
pg_roles | database roles
pg_rules | rules
pg_seclabels | security roles
pg_settings | parameter settings
pg_shadow | database users
pg_stats | planner statistics
pg_tables | tables
pg_timezone_abbrevs | time zone abbreviations
pg_timezone_names | time zone names
pg_user | database users
pg_user_mappings | user mappings
pg_views | views

#### 50.58. `pg_available_extensions`

The `pg_available_extensions` view lists the extensions that are available for installation. See also the `pg_extension` catalog, which shows the extensions currently installed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>default_version</td>
<td>text</td>
<td>Name of default version, or NULL if none is specified</td>
</tr>
<tr>
<td>installed_version</td>
<td>text</td>
<td>Currently installed version of the extension, or NULL if not installed</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The `pg_available_extensions` view is read only.
50.59. pg_available_extension_versions

The pg_available_extension_versions view lists the specific extension versions that are available for installation. See also the pg_extension catalog, which shows the extensions currently installed.

Table 50-60. pg_available_extension_versions Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>Extension name</td>
</tr>
<tr>
<td>version</td>
<td>text</td>
<td>Version name</td>
</tr>
<tr>
<td>installed</td>
<td>bool</td>
<td>True if this version of this extension is currently installed</td>
</tr>
<tr>
<td>superuser</td>
<td>bool</td>
<td>True if only superusers are allowed to install this extension</td>
</tr>
<tr>
<td>relocatable</td>
<td>bool</td>
<td>True if extension can be relocated to another schema</td>
</tr>
<tr>
<td>schema</td>
<td>name</td>
<td>Name of the schema that the extension must be installed into, or NULL if partially or fully relocatable</td>
</tr>
<tr>
<td>requires</td>
<td>name[]</td>
<td>Names of prerequisite extensions, or NULL if none</td>
</tr>
<tr>
<td>comment</td>
<td>text</td>
<td>Comment string from the extension’s control file</td>
</tr>
</tbody>
</table>

The pg_available_extension_versions view is read only.

50.60. pg_config

The view pg_config describes the compile-time configuration parameters of the currently installed version of PostgreSQL. It is intended, for example, to be used by software packages that want to interface to PostgreSQL to facilitate finding the required header files and libraries. It provides the same basic information as the pg_config PostgreSQL client application.

By default, the pg_config view can be read only by superusers.

Table 50-61. pg_config Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>The parameter value</td>
</tr>
</tbody>
</table>

50.61. pg_cursors

The pg_cursors view lists the cursors that are currently available. Cursors can be defined in several
ways:

- via the DECLARE statement in SQL
- via the Bind message in the frontend/backend protocol, as described in Section 51.2.3
- via the Server Programming Interface (SPI), as described in Section 45.1

The `pg_cursors` view displays cursors created by any of these means. Cursors only exist for the duration of the transaction that defines them, unless they have been declared with `WITH HOLD`. Therefore non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Cursors are used internally to implement some of the components of PostgreSQL, such as procedural languages. Therefore, the `pg_cursors` view might include cursors that have not been explicitly created by the user.

### Table 50-62. `pg_cursors` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The name of the cursor</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The verbatim query string submitted to declare this cursor</td>
</tr>
<tr>
<td>is_holdable</td>
<td>boolean</td>
<td><code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise</td>
</tr>
<tr>
<td>is_binary</td>
<td>boolean</td>
<td><code>true</code> if the cursor was declared <code>BINARY</code>; <code>false</code> otherwise</td>
</tr>
<tr>
<td>is_scrollable</td>
<td>boolean</td>
<td><code>true</code> if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise</td>
</tr>
<tr>
<td>creation_time</td>
<td>timestamptz</td>
<td>The time at which the cursor was declared</td>
</tr>
</tbody>
</table>

The `pg_cursors` view is read only.

### 50.62. `pg_file_settings`

The view `pg_file_settings` provides a summary of the contents of the server’s configuration file(s). A row appears in this view for each “name = value” entry appearing in the files, with annotations indicating whether the value could be applied successfully. Additional row(s) may appear for problems not linked to a “name = value” entry, such as syntax errors in the files.

This view is helpful for checking whether planned changes in the configuration files will work, or for diagnosing a previous failure. Note that this view reports on the *current* contents of the files, not on what was last applied by the server. (The `pg_settings` view is usually sufficient to determine that.)
By default, the `pg_file_settings` view can be read only by superusers.

Table 50-63. `pg_file_settings` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Full path name of the configuration file</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file where the entry appears</td>
</tr>
<tr>
<td>seqno</td>
<td>integer</td>
<td>Order in which the entries are processed (1..n)</td>
</tr>
<tr>
<td>name</td>
<td>text</td>
<td>Configuration parameter name</td>
</tr>
<tr>
<td>setting</td>
<td>text</td>
<td>Value to be assigned to the parameter</td>
</tr>
<tr>
<td>applied</td>
<td>boolean</td>
<td>True if the value can be applied successfully</td>
</tr>
<tr>
<td>error</td>
<td>text</td>
<td>If not null, an error message indicating why this entry could not be applied</td>
</tr>
</tbody>
</table>

If the configuration file contains syntax errors or invalid parameter names, the server will not attempt to apply any settings from it, and therefore all the `applied` fields will read as false. In such a case there will be one or more rows with non-null `error` fields indicating the problem(s). Otherwise, individual settings will be applied if possible. If an individual setting cannot be applied (e.g., invalid value, or the setting cannot be changed after server start) it will have an appropriate message in the `error` field. Another way that an entry might have `applied` = false is that it is overridden by a later entry for the same parameter name; this case is not considered an error so nothing appears in the `error` field.

See Section 19.1 for more information about the various ways to change run-time parameters.

50.63. `pg_group`

The view `pg_group` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows the names and members of all roles that are marked as not `rolcanlogin`, which is an approximation to the set of roles that are being used as groups.

Table 50-64. `pg_group` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groname</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>Name of the group</td>
</tr>
<tr>
<td>grossysid</td>
<td>oid</td>
<td><code>pg_authid.oid</code></td>
<td>ID of this group</td>
</tr>
<tr>
<td>grolist</td>
<td>oid[]</td>
<td><code>pg_authid.oid</code></td>
<td>An array containing the IDs of the roles in this group</td>
</tr>
</tbody>
</table>
50.64. pg_indexes

The view `pg_indexes` provides access to useful information about each index in the database.

Table 50-65. pg_indexes Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td><code>pg_namespace.nspname</code></td>
<td>Name of schema containing table and index</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of table the index is for</td>
</tr>
<tr>
<td>indexname</td>
<td>name</td>
<td><code>pg_class.relname</code></td>
<td>Name of index</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td><code>pg_tablespace.spcname</code></td>
<td>Name of tablespace containing index (null if default for database)</td>
</tr>
<tr>
<td>indexdef</td>
<td>text</td>
<td></td>
<td>Index definition (a reconstructed CREATE INDEX command)</td>
</tr>
</tbody>
</table>

50.65. pg_locks

The view `pg_locks` provides access to information about the locks held by active processes within the database server. See Chapter 13 for more discussion of locking.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant process. Thus, the same lockable object might appear many times, if multiple processes are holding or waiting for locks on it. However, an object that currently has no locks on it will not appear at all.

There are several distinct types of lockable objects: whole relations (e.g., tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects (identified by class OID and object OID, in the same way as in `pg_description` or `pg_depend`). Also, the right to extend a relation is represented as a separate lockable object. Also, “advisory” locks can be taken on numbers that have user-defined meanings.

Table 50-66. pg_locks Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locktype</td>
<td>text</td>
<td></td>
<td>Type of the lockable object: relation, extend, page, tuple, transactionid, virtualxid, object, userlock, or advisory</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>database</td>
<td>oid</td>
<td>pg_database.oid</td>
<td>OID of the database in which the lock target exists, or zero if the target is a shared object, or null if the target is a transaction ID</td>
</tr>
<tr>
<td>relation</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the relation targeted by the lock, or null if the target is not a relation or part of a relation</td>
</tr>
<tr>
<td>page</td>
<td>integer</td>
<td></td>
<td>Page number targeted by the lock within the relation, or null if the target is not a relation page or tuple</td>
</tr>
<tr>
<td>tuple</td>
<td>smallint</td>
<td></td>
<td>Tuple number targeted by the lock within the page, or null if the target is not a tuple</td>
</tr>
<tr>
<td>virtualxid</td>
<td>text</td>
<td></td>
<td>Virtual ID of the transaction targeted by the lock, or null if the target is not a virtual transaction ID</td>
</tr>
<tr>
<td>transactionid</td>
<td>xid</td>
<td></td>
<td>ID of the transaction targeted by the lock, or null if the target is not a transaction ID</td>
</tr>
<tr>
<td>classid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>OID of the system catalog containing the lock target, or null if the target is not a general database object</td>
</tr>
<tr>
<td>objid</td>
<td>oid</td>
<td>any OID column</td>
<td>OID of the lock target within its system catalog, or null if the target is not a general database object</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>objsubid</td>
<td>smallint</td>
<td></td>
<td>Column number targeted by the lock (the <code>classid</code> and <code>objid</code> refer to the table itself), or zero if the target is some other general database object, or null if the target is not a general database object.</td>
</tr>
<tr>
<td>virtualtransaction</td>
<td>text</td>
<td></td>
<td>Virtual ID of the transaction that is holding or awaiting this lock.</td>
</tr>
<tr>
<td>pid</td>
<td>integer</td>
<td></td>
<td>Process ID of the server process holding or awaiting this lock, or null if the lock is held by a prepared transaction.</td>
</tr>
<tr>
<td>mode</td>
<td>text</td>
<td></td>
<td>Name of the lock mode held or desired by this process (see Section 13.3.1 and Section 13.2.3).</td>
</tr>
<tr>
<td>granted</td>
<td>boolean</td>
<td></td>
<td>True if lock is held, false if lock is awaited.</td>
</tr>
<tr>
<td>fastpath</td>
<td>boolean</td>
<td></td>
<td>True if lock was taken via fast path, false if taken via main lock table.</td>
</tr>
</tbody>
</table>

`granted` is true in a row representing a lock held by the indicated process. False indicates that this process is currently waiting to acquire this lock, which implies that at least one other process is holding or waiting for a conflicting lock mode on the same lockable object. The waiting process will sleep until the other lock is released (or a deadlock situation is detected). A single process can be waiting to acquire at most one lock at a time.

Throughout running a transaction, a server process holds an exclusive lock on the transaction’s virtual transaction ID. If a permanent ID is assigned to the transaction (which normally happens only if the transaction changes the state of the database), it also holds an exclusive lock on the transaction’s permanent transaction ID until it ends. When a process finds it necessary to wait specifically for another transaction to end, it does so by attempting to acquire share lock on the other transaction’s ID (either virtual or permanent ID depending on the situation). That will succeed only when the other transaction terminates and releases its locks.

Although tuples are a lockable type of object, information about row-level locks is stored on disk, not in memory, and therefore row-level locks normally do not appear in this view. If a process is waiting for a row-level lock, it will usually appear in the view as waiting for the permanent transaction ID of the current holder of that row lock.
Advisory locks can be acquired on keys consisting of either a single \texttt{bigint} value or two integer values. A \texttt{bigint} key is displayed with its high-order half in the \texttt{classid} column, its low-order half in the \texttt{objid} column, and \texttt{objsubid} equal to 1. The original \texttt{bigint} value can be reassembled with the expression \texttt{(classid::bigint \ll 32) | objid::bigint}. Integer keys are displayed with the first key in the \texttt{classid} column, the second key in the \texttt{objid} column, and \texttt{objsubid} equal to 2. The actual meaning of the keys is up to the user. Advisory locks are local to each database, so the database column is meaningful for an advisory lock.

\texttt{pg_locks} provides a global view of all locks in the database cluster, not only those relevant to the current database. Although its relation column can be joined against \texttt{pg_class.oid} to identify locked relations, this will only work correctly for relations in the current database (those for which the database column is either the current database’s OID or zero).

The \texttt{pid} column can be joined to the \texttt{pid} column of the \texttt{pg_stat_activity} view to get more information on the session holding or awaiting each lock, for example:

\begin{verbatim}
SELECT * FROM pg_locks pl LEFT JOIN pg_stat_activity psa
  ON pl.pid = psa.pid;
\end{verbatim}

Also, if you are using prepared transactions, the \texttt{virtualtransaction} column can be joined to the \texttt{transaction} column of the \texttt{pg_prepared_xacts} view to get more information on prepared transactions that hold locks. (A prepared transaction can never be waiting for a lock, but it continues to hold the locks it acquired while running.) For example:

\begin{verbatim}
SELECT * FROM pg_locks pl LEFT JOIN pg_prepared_xacts ppx
  ON pl.virtualtransaction = '-1/' || ppx.transaction;
\end{verbatim}

While it is possible to obtain information about which processes block which other processes by joining \texttt{pg_locks} against itself, this is very difficult to get right in detail. Such a query would have to encode knowledge about which lock modes conflict with which others. Worse, the \texttt{pg_locks} view does not expose information about which processes are ahead of which others in lock wait queues, nor information about which processes are parallel workers running on behalf of which other client sessions. It is better to use the \texttt{pg_blocking_pids()} function (see Table 9-59) to identify which process(es) a waiting process is blocked behind.

The \texttt{pg_locks} view displays data from both the regular lock manager and the predicate lock manager, which are separate systems; in addition, the regular lock manager subdivides its locks into regular and \texttt{fast-path} locks. This data is not guaranteed to be entirely consistent. When the view is queried, data on fast-path locks (with \texttt{fastpath = true}) is gathered from each backend one at a time, without freezing the state of the entire lock manager, so it is possible for locks to be taken or released while information is gathered. Note, however, that these locks are known not to conflict with any other lock currently in place. After all backends have been queried for fast-path locks, the remainder of the regular lock manager is locked as a unit, and a consistent snapshot of all remaining locks is collected as an atomic action. After unlocking the regular lock manager, the predicate lock manager is similarly locked and all predicate locks are collected as an atomic action. Thus, with the exception of fast-path locks, each lock manager will deliver a consistent set of results, but as we do not lock both lock managers simultaneously, it is possible for locks to be taken or released after we interrogate the regular lock manager and before we interrogate the predicate lock manager.

Locking the regular and/or predicate lock manager could have some impact on database performance if this view is very frequently accessed. The locks are held only for the minimum amount of time necessary to obtain data from the lock managers, but this does not completely eliminate the possibility of a performance impact.
50.66. pg_matviews

The view `pg_matviews` provides access to useful information about each materialized view in the database.

**Table 50-67. pg_matviews Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing materialized view</td>
</tr>
<tr>
<td>matviewname</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of materialized view</td>
</tr>
<tr>
<td>matviewowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of materialized view’s owner</td>
</tr>
<tr>
<td>tablespace</td>
<td>name</td>
<td>pg_tablespace.spcname</td>
<td>Name of tablespace containing materialized view (null if default for database)</td>
</tr>
<tr>
<td>hasindexes</td>
<td>boolean</td>
<td></td>
<td>True if materialized view has (or recently had) any indexes</td>
</tr>
<tr>
<td>ispopulated</td>
<td>boolean</td>
<td></td>
<td>True if materialized view is currently populated</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Materialized view definition (a reconstructed SELECT query)</td>
</tr>
</tbody>
</table>

50.67. pg_policies

The view `pg_policies` provides access to useful information about each row-level security policy in the database.

**Table 50-68. pg_policies Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table policy is on</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table policy is on</td>
</tr>
<tr>
<td>policyname</td>
<td>name</td>
<td>pg_policy.polname</td>
<td>Name of policy</td>
</tr>
<tr>
<td>roles</td>
<td>name[]</td>
<td></td>
<td>The roles to which this policy applies</td>
</tr>
</tbody>
</table>
### 50.68. pg_prepared_statements

The `pg_prepared_statements` view displays all the prepared statements that are available in the current session. See `PREPARE` for more information about prepared statements.

`pg_prepared_statements` contains one row for each prepared statement. Rows are added to the view when a new prepared statement is created and removed when a prepared statement is released (for example, via the `DEALLOCATE` command).

#### Table 50-69. pg_prepared_statements Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>The identifier of the prepared statement</td>
</tr>
<tr>
<td>statement</td>
<td>text</td>
<td>The query string submitted by the client to create this prepared statement. For prepared statements created via SQL, this is the <code>PREPARE</code> statement submitted by the client. For prepared statements created via the frontend/backend protocol, this is the text of the prepared statement itself.</td>
</tr>
<tr>
<td>prepare_time</td>
<td>timestamptz</td>
<td>The time at which the prepared statement was created</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter_types</td>
<td>regtype[]</td>
<td>The expected parameter types for the prepared statement in the form of an array of regtype. The OID corresponding to an element of this array can be obtained by casting the regtype value to oid.</td>
</tr>
<tr>
<td>from_sql</td>
<td>boolean</td>
<td>true if the prepared statement was created via the PREPARE SQL command; false if the statement was prepared via the frontend/backend protocol</td>
</tr>
</tbody>
</table>

The `pg_prepared_statements` view is read only.

### 50.69. `pg_prepared_xacts`

The view `pg_prepared_xacts` displays information about transactions that are currently prepared for two-phase commit (see PREPARE TRANSACTION for details).

`pg_prepared_xacts` contains one row per prepared transaction. An entry is removed when the transaction is committed or rolled back.

#### Table 50-70. `pg_prepared_xacts` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transaction</td>
<td>xid</td>
<td></td>
<td>Numeric transaction identifier of the prepared transaction</td>
</tr>
<tr>
<td>gid</td>
<td>text</td>
<td></td>
<td>Global transaction identifier that was assigned to the transaction</td>
</tr>
<tr>
<td>prepared</td>
<td>timestamp with time zone</td>
<td></td>
<td>Time at which the transaction was prepared for commit</td>
</tr>
<tr>
<td>owner</td>
<td>name</td>
<td><code>pg_authid.rolname</code></td>
<td>Name of the user that executed the transaction</td>
</tr>
<tr>
<td>database</td>
<td>name</td>
<td><code>pg_database.datname</code></td>
<td>Name of the database in which the transaction was executed</td>
</tr>
</tbody>
</table>

When the `pg_prepared_xacts` view is accessed, the internal transaction manager data structures are momentarily locked, and a copy is made for the view to display. This ensures that the view produces a consistent set of results, while not blocking normal operations longer than necessary. Nonetheless
there could be some impact on database performance if this view is frequently accessed.

### 50.70. `pg_replication_origin_status` View

The `pg_replication_origin_status` view contains information about how far replay for a certain origin has progressed. For more on replication origins see Chapter 48.

Table 50-71. `pg_replication_origin_status` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_id</td>
<td>Oid</td>
<td><code>pg_replication_origin.roident</code></td>
<td><code>internal_node_identifier</code></td>
</tr>
<tr>
<td>external_id</td>
<td>text</td>
<td><code>pg_replication_origin.roname</code></td>
<td><code>external_node_identifier</code></td>
</tr>
<tr>
<td>remote_lsn</td>
<td><code>pg_lsn</code></td>
<td></td>
<td>The origin node’s LSN up to which data has been replicated.</td>
</tr>
<tr>
<td>local_lsn</td>
<td><code>pg_lsn</code></td>
<td></td>
<td>This node’s LSN at which <code>remote_lsn</code> has been replicated. Used to flush commit records before persisting data to disk when using asynchronous commits.</td>
</tr>
</tbody>
</table>

### 50.71. `pg_replication_slots` View

The `pg_replication_slots` view provides a listing of all replication slots that currently exist on the database cluster, along with their current state.

For more on replication slots, see Section 26.2.6 and Chapter 47.

Table 50-72. `pg_replication_slots` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>slot_name</td>
<td>name</td>
<td></td>
<td>A unique, cluster-wide identifier for the replication slot</td>
</tr>
<tr>

<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>confirmed_flush_lsn</td>
<td>pg_lsn</td>
<td></td>
<td>The address (LSN) up to which the logical slot’s consumer has confirmed receiving data. Data older than this is not available anymore. NULL for physical slots.</td>
</tr>
</tbody>
</table>

50.72. pg_roles

The view pg_roles provides access to information about database roles. This is simply a publicly readable view of pg_authid that blanks out the password field.

This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

Table 50-73. pg_roles Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>Role is a replication role. A replication role can initiate replication connections and create and drop replication slots.</td>
</tr>
<tr>
<td>rolconnlimit</td>
<td>int4</td>
<td></td>
<td>For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit.</td>
</tr>
</tbody>
</table>
Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rolpassword</td>
<td>text</td>
<td></td>
<td>Not the password (always reads as *********)</td>
</tr>
<tr>
<td>rolvaliduntil</td>
<td>timestamptz</td>
<td></td>
<td>Password expiry time (only used for password authentication); null if no expiration</td>
</tr>
<tr>
<td>rolbypassrls</td>
<td>bool</td>
<td></td>
<td>Role bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>rolconfig</td>
<td>text[]</td>
<td></td>
<td>Role-specific defaults for run-time configuration variables</td>
</tr>
<tr>
<td>oid</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>ID of role</td>
</tr>
</tbody>
</table>

### 50.73. pg_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

**Table 50-74. pg_rules Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing table</td>
</tr>
<tr>
<td>tablename</td>
<td>name</td>
<td>pg_class.relname</td>
<td>Name of table the rule is for</td>
</tr>
<tr>
<td>rulename</td>
<td>name</td>
<td>pg_rewrite.rulename</td>
<td>Name of rule</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>Rule definition (a reconstructed creation command)</td>
</tr>
</tbody>
</table>

The `pg_rules` view excludes the ON SELECT rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

### 50.74. pg_seclabels

The view `pg_seclabels` provides information about security labels. It is an easier-to-query version of the `pg_seclabel` catalog.

**Table 50-75. pg_seclabels Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
</table>

2032
### Chapter 50. System Catalogs

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objoid</td>
<td>oid</td>
<td>any OID column</td>
<td>The OID of the object this security label pertains to</td>
</tr>
<tr>
<td>classoid</td>
<td>oid</td>
<td>pg_class.oid</td>
<td>The OID of the system catalog this object appears in</td>
</tr>
<tr>
<td>objsubid</td>
<td>int4</td>
<td></td>
<td>For a security label on a table column, this is the column number</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(the objoid and classoid refer to the table itself). For all other object</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>types, this column is zero.</td>
</tr>
<tr>
<td>objtype</td>
<td>text</td>
<td></td>
<td>The type of object to which this label applies, as text.</td>
</tr>
<tr>
<td>objnamespace</td>
<td>oid</td>
<td>pg_namespace.oid</td>
<td>The OID of the namespace for this object, if applicable; otherwise NULL.</td>
</tr>
<tr>
<td>objname</td>
<td>text</td>
<td></td>
<td>The name of the object to which this label applies, as text.</td>
</tr>
<tr>

<td>The security label applied to this object.</td>
</tr>
</tbody>
</table>

### 50.75. pg_settings

The view `pg_settings` provides access to run-time parameters of the server. It is essentially an alternative interface to the SHOW and SET commands. It also provides access to some facts about each parameter that are not directly available from SHOW, such as minimum and maximum values.

#### Table 50-76. pg_settings Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>

</tr>
<tr>
<td>boot_val</td>
<td>text</td>
<td>Parameter value assumed at server startup if the parameter is not otherwise set</td>
</tr>
<tr>
<td>reset_val</td>
<td>text</td>
<td>Value that RESET would reset the parameter to in the current session</td>
</tr>
<tr>
<td>sourcefile</td>
<td>text</td>
<td>Configuration file the current value was set in (null for values set from sources other than configuration files, or when examined by a non-superuser); helpful when using include directives in configuration files</td>
</tr>
<tr>
<td>sourceline</td>
<td>integer</td>
<td>Line number within the configuration file the current value was set at (null for values set from sources other than configuration files, or when examined by a non-superuser)</td>
</tr>
<tr>
<td>pending_restart</td>
<td>boolean</td>
<td>true if the value has been changed in the configuration file but needs a restart; or false otherwise.</td>
</tr>
</tbody>
</table>

There are several possible values of `context`. In order of decreasing difficulty of changing the setting, they are:

- `internal`

These settings cannot be changed directly; they reflect internally determined values. Some of them may be adjustable by rebuilding the server with different configuration options, or by changing options supplied to `initdb`.  

---

2034
postmaster

These settings can only be applied when the server starts, so any change requires restarting the server. Values for these settings are typically stored in the `postgresql.conf` file, or passed on the command line when starting the server. Of course, settings with any of the lower context types can also be set at server start time.

sighup

Changes to these settings can be made in `postgresql.conf` without restarting the server. Send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf` and apply the changes. The postmaster will also forward the SIGHUP signal to its child processes so that they all pick up the new value.

superuser-backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq’s `PGOPTIONS` environment variable), but only if the connecting user is a superuser. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

backend

Changes to these settings can be made in `postgresql.conf` without restarting the server. They can also be set for a particular session in the connection request packet (for example, via libpq’s `PGOPTIONS` environment variable); any user can make such a change for their session. However, these settings never change in a session after it is started. If you change them in `postgresql.conf`, send a SIGHUP signal to the postmaster to cause it to re-read `postgresql.conf`. The new values will only affect subsequently-launched sessions.

superuser

These settings can be set from `postgresql.conf`, or within a session via the `SET` command; but only superusers can change them via `SET`. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

user

These settings can be set from `postgresql.conf`, or within a session via the `SET` command. Any user is allowed to change their session-local value. Changes in `postgresql.conf` will affect existing sessions only if no session-local value has been established with `SET`.

See Section 19.1 for more information about the various ways to change these parameters.

The `pg_settings` view cannot be inserted into or deleted from, but it can be updated. An `UPDATE` applied to a row of `pg_settings` is equivalent to executing the `SET` command on that named parameter. The change only affects the value used by the current session. If an `UPDATE` is issued within a transaction that is later aborted, the effects of the `UPDATE` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `UPDATE` or `SET`.

50.76. pg_shadow

The view `pg_shadow` exists for backwards compatibility: it emulates a catalog that existed in PostgreSQL before version 8.1. It shows properties of all roles that are marked as `rolcanlogin` in `pg_authid`. 
The name stems from the fact that this table should not be readable by the public since it contains passwords. `pg_user` is a publicly readable view on `pg_shadow` that blanks out the password field.

### Table 50-77. `pg_shadow` Columns

<table>
<thead>

</tr>
</tbody>
</table>

### 50.77. `pg_stats`

The view `pg_stats` provides access to the information stored in the `pg_statistic` catalog. This view allows access only to rows of `pg_statistic` that correspond to tables the user has permission to read, and therefore it is safe to allow public read access to this view.

`pg_stats` is also designed to present the information in a more readable format than the underlying catalog — at the cost that its schema must be extended whenever new slot types are defined for `pg_statistic`.

### Table 50-78. `pg_stats` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>rowsecurity</td>
<td>boolean</td>
<td>pg_class.relrowsecurity</td>
<td>True if row security is enabled on the table</td>
</tr>
</tbody>
</table>

#### 50.79. pg_timezone_abbrevs

The view `pg_timezone_abbrevs` provides a list of time zone abbreviations that are currently recognized by the datetime input routines. The contents of this view change when the timezone_abbreviations run-time parameter is modified.

**Table 50-80. pg_timezone_abbrevs Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if this is a daylight-savings abbreviation</td>
</tr>
</tbody>
</table>

While most timezone abbreviations represent fixed offsets from UTC, there are some that have historically varied in value (see Section B.4 for more information). In such cases this view presents their current meaning.

#### 50.80. pg_timezone_names

The view `pg_timezone_names` provides a list of time zone names that are recognized by `SET TIMEZONE`, along with their associated abbreviations, UTC offsets, and daylight-savings status. (Technically, PostgreSQL does not use UTC because leap seconds are not handled.) Unlike the abbreviations shown in `pg_timezone_abbrevs`, many of these names imply a set of daylight-savings transition date rules. Therefore, the associated information changes across local DST boundaries. The displayed information is computed based on the current value of `CURRENT_TIMESTAMP`.

**Table 50-81. pg_timezone_names Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>text</td>
<td>Time zone name</td>
</tr>
<tr>
<td>abbrev</td>
<td>text</td>
<td>Time zone abbreviation</td>
</tr>
<tr>
<td>utc_offset</td>
<td>interval</td>
<td>Offset from UTC (positive means east of Greenwich)</td>
</tr>
</tbody>
</table>
**Chapter 50. System Catalogs**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>is_dst</td>
<td>boolean</td>
<td>True if currently observing</td>
</tr>
<tr>
<td></td>
<td></td>
<td>daylight savings</td>
</tr>
</tbody>
</table>

### 50.81. pg_user

The view `pg_user` provides access to information about database users. This is simply a publicly readable view of `pg_shadow` that blanks out the password field.

**Table 50-82. pg_user Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>usename</td>
<td>name</td>
<td>User name</td>
</tr>
<tr>
<td>usesysid</td>
<td>oid</td>
<td>ID of this user</td>
</tr>
<tr>
<td>usecreatedb</td>
<td>bool</td>
<td>User can create databases</td>
</tr>
<tr>
<td>usesuper</td>
<td>bool</td>
<td>User is a superuser</td>
</tr>
<tr>
<td>userrepl</td>
<td>bool</td>
<td>User can initiate streaming replication and put the system in and out of backup mode.</td>
</tr>
<tr>
<td>usebypassrls</td>
<td>bool</td>
<td>User bypasses every row level security policy, see Section 5.7 for more information.</td>
</tr>
<tr>
<td>passwd</td>
<td>text</td>
<td>Not the password (always reads as ********)</td>
</tr>
<tr>
<td>valuntil</td>
<td>abstime</td>
<td>Password expiry time (only used for password authentication)</td>
</tr>
<tr>
<td>useconfig</td>
<td>text[]</td>
<td>Session defaults for run-time configuration variables</td>
</tr>
</tbody>
</table>

### 50.82. pg_user_mappings

The view `pg_user_mappings` provides access to information about user mappings. This is essentially a publicly readable view of `pg_user_mapping` that leaves out the options field if the user has no rights to use it.

**Table 50-83. pg_user_mappings Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>umid</td>
<td>oid</td>
<td>pg_user_mapping.oid</td>
<td>OID of the user mapping</td>
</tr>
<tr>
<td>srvid</td>
<td>oid</td>
<td>pg_foreign_server.oid</td>
<td>The OID of the foreign server that contains this mapping</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>References</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>---------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>srvname</td>
<td>name</td>
<td>pg_foreign_server.srvname</td>
<td>Name of the foreign server</td>
</tr>
<tr>
<td>umuser</td>
<td>oid</td>
<td>pg_authid.oid</td>
<td>OID of the local role being mapped, 0 if the user mapping is public</td>
</tr>
<tr>
<td>username</td>
<td>name</td>
<td></td>
<td>Name of the local user to be mapped</td>
</tr>
<tr>
<td>umoptions</td>
<td>text[]</td>
<td></td>
<td>User mapping specific options, as “keyword=value” strings</td>
</tr>
</tbody>
</table>

To protect password information stored as a user mapping option, the `umoptions` column will read as null unless one of the following applies:

- current user is the user being mapped, and owns the server or holds `USAGE` privilege on it
- current user is the server owner and mapping is for `PUBLIC`
- current user is a superuser

### 50.83. pg_views

The view `pg_views` provides access to useful information about each view in the database.

#### Table 50-84. pg_views Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schemaname</td>
<td>name</td>
<td>pg_namespace.nspname</td>
<td>Name of schema containing view</td>
</tr>
<tr>

<tr>
<td>viewowner</td>
<td>name</td>
<td>pg_authid.rolname</td>
<td>Name of view’s owner</td>
</tr>
<tr>
<td>definition</td>
<td>text</td>
<td></td>
<td>View definition (a reconstructed <code>SELECT</code> query)</td>
</tr>
</tbody>
</table>
Chapter 51. Frontend/Backend Protocol

PostgreSQL uses a message-based protocol for communication between frontends and backends (clients and servers). The protocol is supported over TCP/IP and also over Unix-domain sockets. Port number 5432 has been registered with IANA as the customary TCP port number for servers supporting this protocol, but in practice any non-privileged port number can be used.

This document describes version 3.0 of the protocol, implemented in PostgreSQL 7.4 and later. For descriptions of the earlier protocol versions, see previous releases of the PostgreSQL documentation. A single server can support multiple protocol versions. The initial startup-request message tells the server which protocol version the client is attempting to use. If the major version requested by the client is not supported by the server, the connection will be rejected (for example, this would occur if the client requested protocol version 4.0, which does not exist as of this writing). If the minor version requested by the client is not supported by the server (e.g. the client requests version 3.1, but the server supports only 3.0), the server may either reject the connection or may respond with a NegotiateProtocolVersion message containing the highest minor protocol version which it supports. The client may then choose either to continue with the connection using the specified protocol version or to abort the connection.

In order to serve multiple clients efficiently, the server launches a new “backend” process for each client. In the current implementation, a new child process is created immediately after an incoming connection is detected. This is transparent to the protocol, however. For purposes of the protocol, the terms “backend” and “server” are interchangeable; likewise “frontend” and “client” are interchangeable.

51.1. Overview

The protocol has separate phases for startup and normal operation. In the startup phase, the frontend opens a connection to the server and authenticates itself to the satisfaction of the server. (This might involve a single message, or multiple messages depending on the authentication method being used.) If all goes well, the server then sends status information to the frontend, and finally enters normal operation. Except for the initial startup-request message, this part of the protocol is driven by the server.

During normal operation, the frontend sends queries and other commands to the backend, and the backend sends back query results and other responses. There are a few cases (such as NOTIFY) wherein the backend will send unsolicited messages, but for the most part this portion of a session is driven by frontend requests.

Termination of the session is normally by frontend choice, but can be forced by the backend in certain cases. In any case, when the backend closes the connection, it will roll back any open (incomplete) transaction before exiting.

Within normal operation, SQL commands can be executed through either of two sub-protocols. In the “simple query” protocol, the frontend just sends a textual query string, which is parsed and immediately executed by the backend. In the “extended query” protocol, processing of queries is separated into multiple steps: parsing, binding of parameter values, and execution. This offers flexibility and performance benefits, at the cost of extra complexity.

Normal operation has additional sub-protocols for special operations such as COPY.
51.1.1. Messaging Overview

All communication is through a stream of messages. The first byte of a message identifies the message type, and the next four bytes specify the length of the rest of the message (this length count includes itself, but not the message-type byte). The remaining contents of the message are determined by the message type. For historical reasons, the very first message sent by the client (the startup message) has no initial message-type byte.

To avoid losing synchronization with the message stream, both servers and clients typically read an entire message into a buffer (using the byte count) before attempting to process its contents. This allows easy recovery if an error is detected while processing the contents. In extreme situations (such as not having enough memory to buffer the message), the receiver can use the byte count to determine how much input to skip before it resumes reading messages.

Conversely, both servers and clients must take care never to send an incomplete message. This is commonly done by marshaling the entire message in a buffer before beginning to send it. If a communications failure occurs partway through sending or receiving a message, the only sensible response is to abandon the connection, since there is little hope of recovering message-boundary synchronization.

51.1.2. Extended Query Overview

In the extended-query protocol, execution of SQL commands is divided into multiple steps. The state retained between steps is represented by two types of objects: prepared statements and portals. A prepared statement represents the result of parsing and semantic analysis of a textual query string. A prepared statement is not in itself ready to execute, because it might lack specific values for parameters. A portal represents a ready-to-execute or already-partially-executed statement, with any missing parameter values filled in. (For SELECT statements, a portal is equivalent to an open cursor, but we choose to use a different term since cursors don’t handle non-SELECT statements.)

The overall execution cycle consists of a parse step, which creates a prepared statement from a textual query string; a bind step, which creates a portal given a prepared statement and values for any needed parameters; and an execute step that runs a portal’s query. In the case of a query that returns rows (SELECT, SHOW, etc), the execute step can be told to fetch only a limited number of rows, so that multiple execute steps might be needed to complete the operation.

The backend can keep track of multiple prepared statements and portals (but note that these exist only within a session, and are never shared across sessions). Existing prepared statements and portals are referenced by names assigned when they were created. In addition, an “unnamed” prepared statement and portal exist. Although these behave largely the same as named objects, operations on them are optimized for the case of executing a query only once and then discarding it, whereas operations on named objects are optimized on the expectation of multiple uses.

51.1.3. Formats and Format Codes

Data of a particular data type might be transmitted in any of several different formats. As of PostgreSQL 7.4 the only supported formats are “text” and “binary”, but the protocol makes provision for future extensions. The desired format for any value is specified by a format code. Clients can specify a format code for each transmitted parameter value and for each column of a query result. Text has format code zero, binary has format code one, and all other format codes are reserved for future definition.

The text representation of values is whatever strings are produced and accepted by the input/output conversion functions for the particular data type. In the transmitted representation, there is no trailing
null character; the frontend must add one to received values if it wants to process them as C strings. (The text format does not allow embedded nulls, by the way.)

Binary representations for integers use network byte order (most significant byte first). For other data types consult the documentation or source code to learn about the binary representation. Keep in mind that binary representations for complex data types might change across server versions; the text format is usually the more portable choice.

51.2. Message Flow

This section describes the message flow and the semantics of each message type. (Details of the exact representation of each message appear in Section 51.5.) There are several different sub-protocols depending on the state of the connection: start-up, query, function call, \texttt{COPY}, and termination. There are also special provisions for asynchronous operations (including notification responses and command cancellation), which can occur at any time after the start-up phase.

51.2.1. Start-up

To begin a session, a frontend opens a connection to the server and sends a startup message. This message includes the names of the user and of the database the user wants to connect to; it also identifies the particular protocol version to be used. (Optionally, the startup message can include additional settings for run-time parameters.) The server then uses this information and the contents of its configuration files (such as \texttt{pg\_hba\.conf}) to determine whether the connection is provisionally acceptable, and what additional authentication is required (if any).

The server then sends an appropriate authentication request message, to which the frontend must reply with an appropriate authentication response message (such as a password). For all authentication methods except GSSAPI and SSPI, there is at most one request and one response. In some methods, no response at all is needed from the frontend, and so no authentication request occurs. For GSSAPI and SSPI, multiple exchanges of packets may be needed to complete the authentication.

The authentication cycle ends with the server either rejecting the connection attempt (ErrorResponse), or sending AuthenticationOk.

The possible messages from the server in this phase are:

- ErrorResponse
  
  The connection attempt has been rejected. The server then immediately closes the connection.

- AuthenticationOk
  
  The authentication exchange is successfully completed.

- AuthenticationKerberosV5
  
  The frontend must now take part in a Kerberos V5 authentication dialog (not described here, part of the Kerberos specification) with the server. If this is successful, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. This is no longer supported.

- AuthenticationCleartextPassword
  
  The frontend must now send a PasswordMessage containing the password in clear-text form. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse.
AuthenticationMD5Password

The frontend must now send a PasswordMessage containing the password (with user name) encrypted via MD5, then encrypted again using the 4-byte random salt specified in the AuthenticationMD5Password message. If this is the correct password, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. The actual PasswordMessage can be computed in SQL as `concat('md5', md5(concat(md5(concat(password, username)), random-salt)))`. (Keep in mind the `md5()` function returns its result as a hex string.)

AuthenticationSCMCredential

This response is only possible for local Unix-domain connections on platforms that support SCM credential messages. The frontend must issue an SCM credential message and then send a single data byte. (The contents of the data byte are uninteresting; it’s only used to ensure that the server waits long enough to receive the credential message.) If the credential is acceptable, the server responds with an AuthenticationOk, otherwise it responds with an ErrorResponse. (This message type is only issued by pre-9.1 servers. It may eventually be removed from the protocol specification.)

AuthenticationGSS

The frontend must now initiate a GSSAPI negotiation. The frontend will send a PasswordMessage with the first part of the GSSAPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationSSPI

The frontend must now initiate a SSPI negotiation. The frontend will send a PasswordMessage with the first part of the SSPI data stream in response to this. If further messages are needed, the server will respond with AuthenticationGSSContinue.

AuthenticationGSSContinue

This message contains the response data from the previous step of GSSAPI or SSPI negotiation (AuthenticationGSS, AuthenticationSSPI or a previous AuthenticationGSSContinue). If the GSSAPI or SSPI data in this message indicates more data is needed to complete the authentication, the frontend must send that data as another PasswordMessage. If GSSAPI or SSPI authentication is completed by this message, the server will next send AuthenticationOk to indicate successful authentication or ErrorResponse to indicate failure.

NegotiateProtocolVersion

The server does not support the minor protocol version requested by the client, but does support an earlier version of the protocol; this message indicates the highest supported minor version. This message will also be sent if the client requested unsupported protocol options (i.e. beginning with `--pq--`) in the startup packet. This message will be followed by an ErrorResponse or a message indicating the success or failure of authentication.

If the frontend does not support the authentication method requested by the server, then it should immediately close the connection.

After having received AuthenticationOk, the frontend must wait for further messages from the server. In this phase a backend process is being started, and the frontend is just an interested bystander. It is still possible for the startup attempt to fail (ErrorResponse) or the server to decline support for the requested minor protocol version (NegotiateProtocolVersion), but in the normal case the backend will send some ParameterStatus messages, BackendKeyData, and finally ReadyForQuery.
Chapter 51. Frontend/Backend Protocol

During this phase the backend will attempt to apply any additional run-time parameter settings that were given in the startup message. If successful, these values become session defaults. An error causes ErrorResponse and exit.

The possible messages from the backend in this phase are:

**BackendKeyData**

This message provides secret-key data that the frontend must save if it wants to be able to issue cancel requests later. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ParameterStatus**

This message informs the frontend about the current (initial) setting of backend parameters, such as client_encoding or DateStyle. The frontend can ignore this message, or record the settings for its future use; see Section 51.2.6 for more details. The frontend should not respond to this message, but should continue listening for a ReadyForQuery message.

**ReadyForQuery**

Start-up is completed. The frontend can now issue commands.

**ErrorResponse**

Start-up failed. The connection is closed after sending this message.

**NoticeResponse**

A warning message has been issued. The frontend should display the message but continue listening for ReadyForQuery or ErrorResponse.

The ReadyForQuery message is the same one that the backend will issue after each command cycle. Depending on the coding needs of the frontend, it is reasonable to consider ReadyForQuery as starting a command cycle, or to consider ReadyForQuery as ending the start-up phase and each subsequent command cycle.

### 51.2.2. Simple Query

A simple query cycle is initiated by the frontend sending a Query message to the backend. The message includes an SQL command (or commands) expressed as a text string. The backend then sends one or more response messages depending on the contents of the query command string, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new command. (It is not actually necessary for the frontend to wait for ReadyForQuery before issuing another command, but the frontend must then take responsibility for figuring out what happens if the earlier command fails and already-issued later commands succeed.)

The possible response messages from the backend are:

**CommandComplete**

An SQL command completed normally.

**CopyInResponse**

The backend is ready to copy data from the frontend to a table; see Section 51.2.5.

**CopyOutResponse**

The backend is ready to copy data from a table to the frontend; see Section 51.2.5.
Chapter 51. Frontend/Backend Protocol

RowDescription
Indicates that rows are about to be returned in response to a SELECT, FETCH, etc query. The contents of this message describe the column layout of the rows. This will be followed by a DataRow message for each row being returned to the frontend.

DataRow
One of the set of rows returned by a SELECT, FETCH, etc query.

EmptyQueryResponse
An empty query string was recognized.

ErrorResponse
An error has occurred.

ReadyForQuery
Processing of the query string is complete. A separate message is sent to indicate this because the query string might contain multiple SQL commands. (CommandComplete marks the end of processing one SQL command, not the whole string.) ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse
A warning message has been issued in relation to the query. Notices are in addition to other responses, i.e., the backend will continue processing the command.

The response to a SELECT query (or other queries that return row sets, such as EXPLAIN or SHOW) normally consists of RowDescription, zero or more DataRow messages, and then CommandComplete. COPY to or from the frontend invokes special protocol as described in Section 51.2.5. All other query types normally produce only a CommandComplete message.

Since a query string could contain several queries (separated by semicolons), there might be several such response sequences before the backend finishes processing the query string. ReadyForQuery is issued when the entire string has been processed and the backend is ready to accept a new query string.

If a completely empty (no contents other than whitespace) query string is received, the response is EmptyQueryResponse followed by ReadyForQuery.

In the event of an error, ErrorResponse is issued followed by ReadyForQuery. All further processing of the query string is aborted by ErrorResponse (even if more queries remained in it). Note that this might occur partway through the sequence of messages generated by an individual query.

In simple Query mode, the format of retrieved values is always text, except when the given command is a FETCH from a cursor declared with the BINARY option. In that case, the retrieved values are in binary format. The format codes given in the RowDescription message tell which format is being used.

A frontend must be prepared to accept ErrorResponse and NoticeResponse messages whenever it is expecting any other type of message. See also Section 51.2.6 concerning messages that the backend might generate due to outside events.

Recommended practice is to code frontends in a state-machine style that will accept any message type at any time that it could make sense, rather than wiring in assumptions about the exact sequence of messages.
51.2.3. Extended Query

The extended query protocol breaks down the above-described simple query protocol into multiple steps. The results of preparatory steps can be re-used multiple times for improved efficiency. Furthermore, additional features are available, such as the possibility of supplying data values as separate parameters instead of having to insert them directly into a query string.

In the extended protocol, the frontend first sends a Parse message, which contains a textual query string, optionally some information about data types of parameter placeholders, and the name of a destination prepared-statement object (an empty string selects the unnamed prepared statement). The response is either ParseComplete or ErrorResponse. Parameter data types can be specified by OID; if not given, the parser attempts to infer the data types in the same way as it would do for untyped literal string constants.

**Note:** A parameter data type can be left unspecified by setting it to zero, or by making the array of parameter type OIDs shorter than the number of parameter symbols \( n \) used in the query string. Another special case is that a parameter's type can be specified as `void` (that is, the OID of the `void` pseudotype). This is meant to allow parameter symbols to be used for function parameters that are actually OUT parameters. Ordinarily there is no context in which a `void` parameter could be used, but if such a parameter symbol appears in a function's parameter list, it is effectively ignored. For example, a function call such as `foo($1,$2,$3,$4)` could match a function with two IN and two OUT arguments, if \( $3 \) and \( $4 \) are specified as having type `void`.

**Note:** The query string contained in a Parse message cannot include more than one SQL statement; else a syntax error is reported. This restriction does not exist in the simple-query protocol, but it does exist in the extended protocol, because allowing prepared statements or portals to contain multiple commands would complicate the protocol unduly.

If successfully created, a named prepared-statement object lasts till the end of the current session, unless explicitly destroyed. An unnamed prepared statement lasts only until the next Parse statement specifying the unnamed statement as destination is issued. (Note that a simple Query message also destroys the unnamed statement.) Named prepared statements must be explicitly closed before they can be redefined by another Parse message, but this is not required for the unnamed statement. Named prepared statements can also be created and accessed at the SQL command level, using `PREPARE` and `EXECUTE`.

Once a prepared statement exists, it can be readied for execution using a Bind message. The Bind message gives the name of the source prepared statement (empty string denotes the unnamed prepared statement), the name of the destination portal (empty string denotes the unnamed portal), and the values to use for any parameter placeholders present in the prepared statement. The supplied parameter set must match those needed by the prepared statement. (If you declared any `void` parameters in the Parse message, pass NULL values for them in the Bind message.) Bind also specifies the format to use for any data returned by the query; the format can be specified overall, or per-column. The response is either BindComplete or ErrorResponse.

**Note:** The choice between text and binary output is determined by the format codes given in Bind, regardless of the SQL command involved. The `BINARY` attribute in cursor declarations is irrelevant when using extended query protocol.
Query planning typically occurs when the Bind message is processed. If the prepared statement has no parameters, or is executed repeatedly, the server might save the created plan and re-use it during subsequent Bind messages for the same prepared statement. However, it will do so only if it finds that a generic plan can be created that is not much less efficient than a plan that depends on the specific parameter values supplied. This happens transparently so far as the protocol is concerned.

If successfully created, a named portal object lasts till the end of the current transaction, unless explicitly destroyed. An unnamed portal is destroyed at the end of the transaction, or as soon as the next Bind statement specifying the unnamed portal as destination is issued. (Note that a simple Query message also destroys the unnamed portal.) Named portals must be explicitly closed before they can be redefined by another Bind message, but this is not required for the unnamed portal. Named portals can also be created and accessed at the SQL command level, using `DECLARE CURSOR` and `FETCH`.

Once a portal exists, it can be executed using an Execute message. The Execute message specifies the portal name (empty string denotes the unnamed portal) and a maximum result-row count (zero meaning “fetch all rows”). The result-row count is only meaningful for portals containing commands that return row sets; in other cases the command is always executed to completion, and the row count is ignored. The possible responses to Execute are the same as those described above for queries issued via simple query protocol, except that Execute doesn’t cause ReadyForQuery or RowDescription to be issued.

If Execute terminates before completing the execution of a portal (due to reaching a nonzero result-row count), it will send a PortalSuspended message; the appearance of this message tells the frontend that another Execute should be issued against the same portal to complete the operation. The CommandComplete message indicating completion of the source SQL command is not sent until the portal’s execution is completed. Therefore, an Execute phase is always terminated by the appearance of exactly one of these messages: CommandComplete, EmptyQueryResponse (if the portal was created from an empty query string), ErrorResponse, or PortalSuspended.

At completion of each series of extended-query messages, the frontend should issue a Sync message. This parameterless message causes the backend to close the current transaction if it’s not inside a BEGIN/COMMIT transaction block (“close” meaning to commit if no error, or roll back if error). Then a ReadyForQuery response is issued. The purpose of Sync is to provide a resynchronization point for error recovery. When an error is detected while processing any extended-query message, the backend issues ErrorResponse, then reads and discards messages until a Sync is reached, then issues ReadyForQuery and returns to normal message processing. (But note that no skipping occurs if an error is detected while processing Sync — this ensures that there is one and only one ReadyForQuery sent for each Sync.)

**Note:** Sync does not cause a transaction block opened with BEGIN to be closed. It is possible to detect this situation since the ReadyForQuery message includes transaction status information.

In addition to these fundamental, required operations, there are several optional operations that can be used with extended-query protocol.

The Describe message (portal variant) specifies the name of an existing portal (or an empty string for the unnamed portal). The response is a RowDescription message describing the rows that will be returned by executing the portal; or a NoData message if the portal does not contain a query that will return rows; or ErrorResponse if there is no such portal.

The Describe message (statement variant) specifies the name of an existing prepared statement (or an empty string for the unnamed prepared statement). The response is a ParameterDescription message describing the parameters needed by the statement, followed by a RowDescription message describing the rows that will be returned when the statement is eventually executed (or a NoData message if the
statement will not return rows). ErrorResponse is issued if there is no such prepared statement. Note that since Bind has not yet been issued, the formats to be used for returned columns are not yet known to the backend; the format code fields in the RowDescription message will be zeroes in this case.

**Tip:** In most scenarios the frontend should issue one or the other variant of Describe before issuing Execute, to ensure that it knows how to interpret the results it will get back.

The Close message closes an existing prepared statement or portal and releases resources. It is not an error to issue Close against a nonexistent statement or portal name. The response is normally CloseComplete, but could be ErrorResponse if some difficulty is encountered while releasing resources. Note that closing a prepared statement implicitly closes any open portals that were constructed from that statement.

The Flush message does not cause any specific output to be generated, but forces the backend to deliver any data pending in its output buffers. A Flush must be sent after any extended-query command except Sync, if the frontend wishes to examine the results of that command before issuing more commands. Without Flush, messages returned by the backend will be combined into the minimum possible number of packets to minimize network overhead.

**Note:** The simple Query message is approximately equivalent to the series Parse, Bind, portal Describe, Execute, Close, Sync, using the unnamed prepared statement and portal objects and no parameters. One difference is that it will accept multiple SQL statements in the query string, automatically performing the bind/describe/execute sequence for each one in succession. Another difference is that it will not return ParseComplete, BindComplete, CloseComplete, or No-Data messages.

### 51.2.4. Function Call

The Function Call sub-protocol allows the client to request a direct call of any function that exists in the database’s pg_proc system catalog. The client must have execute permission for the function.

**Note:** The Function Call sub-protocol is a legacy feature that is probably best avoided in new code. Similar results can be accomplished by setting up a prepared statement that does `SELECT function($1, ...)`. The Function Call cycle can then be replaced with Bind/Execute.

A Function Call cycle is initiated by the frontend sending a FunctionCall message to the backend. The backend then sends one or more response messages depending on the results of the function call, and finally a ReadyForQuery response message. ReadyForQuery informs the frontend that it can safely send a new query or function call.

The possible response messages from the backend are:

- **ErrorResponse**
  
  An error has occurred.

- **FunctionCallResponse**

  The function call was completed and returned the result given in the message. (Note that the Function Call protocol can only handle a single scalar result, not a row type or set of results.)
ReadyForQuery

Processing of the function call is complete. ReadyForQuery will always be sent, whether processing terminates successfully or with an error.

NoticeResponse

A warning message has been issued in relation to the function call. Notices are in addition to other responses, i.e., the backend will continue processing the command.

51.2.5. COPY Operations

The `COPY` command allows high-speed bulk data transfer to or from the server. Copy-in and copy-out operations each switch the connection into a distinct sub-protocol, which lasts until the operation is completed.

Copy-in mode (data transfer to the server) is initiated when the backend executes a `COPY FROM STDIN` SQL statement. The backend sends a CopyInResponse message to the frontend. The frontend should then send zero or more CopyData messages, forming a stream of input data. (The message boundaries are not required to have anything to do with row boundaries, although that is often a reasonable choice.) The frontend can terminate the copy-in mode by sending either a CopyDone message (allowing successful termination) or a CopyFail message (which will cause the `COPY` SQL statement to fail with an error). The backend then reverts to the command-processing mode it was in before the `COPY` started, which will be either simple or extended query protocol. It will next send either CommandComplete (if successful) or ErrorResponse (if not).

In the event of a backend-detected error during copy-in mode (including receipt of a CopyFail message), the backend will issue an ErrorResponse message. If the `COPY` command was issued via an extended-query message, the backend will now discard frontend messages until a Sync message is received, then it will issue ReadyForQuery and return to normal processing. If the `COPY` command was issued in a simple Query message, the rest of that message is discarded and ReadyForQuery is issued. In either case, any subsequent CopyData, CopyDone, or CopyFail messages issued by the frontend will simply be dropped.

The backend will ignore Flush and Sync messages received during copy-in mode. Receipt of any other non-copy message type constitutes an error that will abort the copy-in state as described above. (The exception for Flush and Sync is for the convenience of client libraries that always send Flush or Sync after an Execute message, without checking whether the command to be executed is a `COPY FROM STDIN`.)

Copy-out mode (data transfer from the server) is initiated when the backend executes a `COPY TO STDOUT` SQL statement. The backend sends a CopyOutResponse message to the frontend, followed by zero or more CopyData messages (always one per row), followed by CopyDone. The backend then reverts to the command-processing mode it was in before the `COPY` started, and sends CommandComplete. The frontend cannot abort the transfer (except by closing the connection or issuing a Cancel request), but it can discard unwanted CopyData and CopyDone messages.

In the event of a backend-detected error during copy-out mode, the backend will issue an ErrorResponse message and revert to normal processing. The frontend should treat receipt of ErrorResponse as terminating the copy-out mode.

It is possible for NoticeResponse and ParameterStatus messages to be interspersed between CopyData messages; frontends must handle these cases, and should be prepared for other asynchronous message types as well (see Section 51.2.6). Otherwise, any message type other than CopyData or CopyDone may be treated as terminating copy-out mode.
There is another Copy-related mode called copy-both, which allows high-speed bulk data transfer to and from the server. Copy-both mode is initiated when a backend in walsender mode executes a START_REPLICATION statement. The backend sends a CopyBothResponse message to the frontend. Both the backend and the frontend may then send CopyData messages until either end sends a CopyDone message. After the client sends a CopyDone message, the connection goes from copy-both mode to copy-out mode, and the client may not send any more CopyData messages. Similarly, when the server sends a CopyDone message, the connection goes into copy-in mode, and the server may not send any more CopyData messages. After both sides have sent a CopyDone message, the copy mode is terminated, and the backend reverts to the command-processing mode.

The CopyInResponse, CopyOutResponse and CopyBothResponse messages include fields that inform the frontend of the number of columns per row and the format codes being used for each column. (As of the present implementation, all columns in a given COPY operation will use the same format, but the message design does not assume this.)

51.2.6. Asynchronous Operations

There are several cases in which the backend will send messages that are not specifically prompted by the frontend’s command stream. Frontends must be prepared to deal with these messages at any time, even when not engaged in a query. At minimum, one should check for these cases before beginning to read a query response.

It is possible for NoticeResponse messages to be generated due to outside activity; for example, if the database administrator commands a “fast” database shutdown, the backend will send a NoticeResponse indicating this fact before closing the connection. Accordingly, frontends should always be prepared to accept and display NoticeResponse messages, even when the connection is nominally idle.

ParameterStatus messages will be generated whenever the active value changes for any of the parameters the backend believes the frontend should know about. Most commonly this occurs in response to a SET SQL command executed by the frontend, and this case is effectively synchronous — but it is also possible for parameter status changes to occur because the administrator changed a configuration file and then sent the SIGHUP signal to the server. Also, if a SET command is rolled back, an appropriate ParameterStatus message will be generated to report the current effective value.

At present there is a hard-wired set of parameters for which ParameterStatus will be generated: they are server_version, server_encoding, client_encoding, application_name, is_superuser, session_authorization, DateStyle, IntervalStyle, TimeZone, integer_datetimes, and standard_conforming_strings. (server_encoding, TimeZone, and integer_datetimes were not reported by releases before 8.0; standard_conforming_strings was not reported by releases before 8.1; IntervalStyle was not reported by releases before 8.4; application_name was not reported by releases before 9.0.) Note that server_version, server_encoding and integer_datetimes are pseudo-parameters that cannot change after startup. This set might change in the future, or even become configurable. Accordingly, a frontend should simply ignore ParameterStatus for parameters that it does not understand or care about.

If a frontend issues a LISTEN command, then the backend will send a NotificationResponse message (not to be confused with NoticeResponse!) whenever a NOTIFY command is executed for the same
channel name.

**Note:** At present, NotificationResponse can only be sent outside a transaction, and thus it will not occur in the middle of a command-response series, though it might occur just before ReadyForQuery. It is unwise to design frontend logic that assumes that, however. Good practice is to be able to accept NotificationResponse at any point in the protocol.

### 51.2.7. Canceling Requests in Progress

During the processing of a query, the frontend might request cancellation of the query. The cancel request is not sent directly on the open connection to the backend for reasons of implementation efficiency: we don’t want to have the backend constantly checking for new input from the frontend during query processing. Cancel requests should be relatively infrequent, so we make them slightly cumbersome in order to avoid a penalty in the normal case.

To issue a cancel request, the frontend opens a new connection to the server and sends a CancelRequest message, rather than the StartupMessage message that would ordinarily be sent across a new connection. The server will process this request and then close the connection. For security reasons, no direct reply is made to the cancel request message.

A CancelRequest message will be ignored unless it contains the same key data (PID and secret key) passed to the frontend during connection start-up. If the request matches the PID and secret key for a currently executing backend, the processing of the current query is aborted. (In the existing implementation, this is done by sending a special signal to the backend process that is processing the query.)

The cancellation signal might or might not have any effect — for example, if it arrives after the backend has finished processing the query, then it will have no effect. If the cancellation is effective, it results in the current command being terminated early with an error message.

The upshot of all this is that for reasons of both security and efficiency, the frontend has no direct way to tell whether a cancel request has succeeded. It must continue to wait for the backend to respond to the query. Issuing a cancel simply improves the odds that the current query will finish soon, and improves the odds that it will fail with an error message instead of succeeding.

Since the cancel request is sent across a new connection to the server and not across the regular frontend/backend communication link, it is possible for the cancel request to be issued by any process, not just the frontend whose query is to be canceled. This might provide additional flexibility when building multiple-process applications. It also introduces a security risk, in that unauthorized persons might try to cancel queries. The security risk is addressed by requiring a dynamically generated secret key to be supplied in cancel requests.

### 51.2.8. Termination

The normal, graceful termination procedure is that the frontend sends a Terminate message and immediately closes the connection. On receipt of this message, the backend closes the connection and terminates.

In rare cases (such as an administrator-commanded database shutdown) the backend might disconnect without any frontend request to do so. In such cases the backend will attempt to send an error or notice message giving the reason for the disconnection before it closes the connection.
Other termination scenarios arise from various failure cases, such as core dump at one end or the other, loss of the communications link, loss of message-boundary synchronization, etc. If either frontend or backend sees an unexpected closure of the connection, it should clean up and terminate. The frontend has the option of launching a new backend by reconnecting the server if it doesn’t want to terminate itself. Closing the connection is also advisable if an unrecognizable message type is received, since this probably indicates loss of message-boundary sync.

For either normal or abnormal termination, any open transaction is rolled back, not committed. One should note however that if a frontend disconnects while a non-SELECT query is being processed, the backend will probably finish the query before noticing the disconnection. If the query is outside any transaction block (BEGIN ... COMMIT sequence) then its results might be committed before the disconnection is recognized.

### 51.2.9. SSL Session Encryption

If PostgreSQL was built with SSL support, frontend/backend communications can be encrypted using SSL. This provides communication security in environments where attackers might be able to capture the session traffic. For more information on encrypting PostgreSQL sessions with SSL, see Section 18.9.

To initiate an SSL-encrypted connection, the frontend initially sends an SSLRequest message rather than a StartupMessage. The server then responds with a single byte containing S or N, indicating that it is willing or unwilling to perform SSL, respectively. The frontend might close the connection at this point if it is dissatisfied with the response. To continue after S, perform an SSL startup handshake (not described here, part of the SSL specification) with the server. If this is successful, continue with sending the usual StartupMessage. In this case the StartupMessage and all subsequent data will be SSL-encrypted. To continue after N, send the usual StartupMessage and proceed without encryption.

The frontend should also be prepared to handle an ErrorMessage response to SSLRequest from the server. This would only occur if the server predates the addition of SSL support to PostgreSQL. (Such servers are now very ancient, and likely do not exist in the wild anymore.) In this case the connection must be closed, but the frontend might choose to open a fresh connection and proceed without requesting SSL.

An initial SSLRequest can also be used in a connection that is being opened to send a CancelRequest message.

While the protocol itself does not provide a way for the server to force SSL encryption, the administrator can configure the server to reject unencrypted sessions as a byproduct of authentication checking.

### 51.3. Streaming Replication Protocol

To initiate streaming replication, the frontend sends the replication parameter in the startup message. A Boolean value of true tells the backend to go into walsender mode, wherein a small set of replication commands can be issued instead of SQL statements. Only the simple query protocol can be used in walsender mode. Replication commands are logged in the server log when log_replication_commands is enabled. Passing database as the value instructs walsender to connect to the database specified in the dbname parameter, which will allow the connection to be used for logical replication from that database.

For the purpose of testing replication commands, you can make a replication connection via psql or any other libpq-using tool with a connection string including the replication option, e.g.:
psql "dbname=postgres replication=database" -c "IDENTIFY_SYSTEM;"

However, it is often more useful to use pg_receivexlog (for physical replication) or pg_recvlogical (for logical replication).

The commands accepted in walsender mode are:

IDENTIFY_SYSTEM

Requests the server to identify itself. Server replies with a result set of a single row, containing four fields:

systemid (text)

The unique system identifier identifying the cluster. This can be used to check that the base backup used to initialize the standby came from the same cluster.

timeline (int4)

Current timeline ID. Also useful to check that the standby is consistent with the master.

xlogfile (text)

Current xlog flush location. Useful to get a known location in the transaction log where streaming can start.

dbname (text)

Database connected to or null.

TIMELINE_HISTORY tli

Requests the server to send over the timeline history file for timeline tli. Server replies with a result set of a single row, containing two fields:

filename (text)

File name of the timeline history file, e.g., 00000002.history.

content (bytea)

Contents of the timeline history file.

CREATE_REPLICATION_SLOT slot_name { PHYSICAL [ RESERVE_WAL ] | LOGICAL output_plugin }

Create a physical or logical replication slot. See Section 26.2.6 for more about replication slots.

slot_name

The name of the slot to create. Must be a valid replication slot name (see Section 26.2.6.1).

output_plugin

The name of the output plugin used for logical decoding (see Section 47.6).

RESERVE_WAL

Specify that this physical replication slot reserves WAL immediately. Otherwise, WAL is only reserved upon connection from a streaming replication client.
Chapter 51. Frontend/Backend Protocol

START_REPLICATION [ SLOT slot_name ] [ PHYSICAL ] XXX/XXX [ TIMELINE tli ]

Instructs server to start streaming WAL, starting at WAL position XXX/XXX. If TIMELINE option is specified, streaming starts on timeline tli; otherwise, the server’s current timeline is selected. The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

If a slot’s name is provided via slot_name, it will be updated as replication progresses so that the server knows which WAL segments, and if hot_standby_feedback is on which transactions, are still needed by the standby.

If the client requests a timeline that’s not the latest but is part of the history of the server, the server will stream all the WAL on that timeline starting from the requested start point up to the point where the server switched to another timeline. If the client requests streaming at exactly the end of an old timeline, the server responds immediately with CommandComplete without entering COPY mode.

After streaming all the WAL on a timeline that is not the latest one, the server will end streaming by exiting the COPY mode. When the client acknowledges this by also exiting COPY mode, the server sends a result set with one row and two columns, indicating the next timeline in this server’s history. The first column is the next timeline’s ID (type int8), and the second column is the WAL position where the switch happened (type text). Usually, the switch position is the end of the WAL that was streamed, but there are corner cases where the server can send some WAL from the old timeline that it has not itself replayed before promoting. Finally, the server sends CommandComplete message, and is ready to accept a new command.

WAL data is sent as a series of CopyData messages. (This allows other information to be intermixed; in particular the server can send an ErrorResponse message if it encounters a failure after beginning to stream.) The payload of each CopyData message from server to the client contains a message of one of the following formats:

XLogData (B)

Byte1(‘w’)

Identifies the message as WAL data.

Int64

The starting point of the WAL data in this message.

Int64

The current end of WAL on the server.

Int64

The server’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte:

A section of the WAL data stream.

A single WAL record is never split across two XLogData messages. When a WAL record crosses a WAL page boundary, and is therefore already split using continuation records, it can be split at the page boundary. In other words, the first main WAL record and its continuation records can be sent in different XLogData messages.
Primary keepalive message (B)

Byte1('k')
Identifies the message as a sender keepalive.

Int64
The current end of WAL on the server.

Int64
The server's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
1 means that the client should reply to this message as soon as possible, to avoid a timeout disconnect. 0 otherwise.

The receiving process can send replies back to the sender at any time, using one of the following message formats (also in the payload of a CopyData message):

Standby status update (F)

Byte1('r')
Identifies the message as a receiver status update.

Int64
The location of the last WAL byte + 1 received and written to disk in the standby.

Int64
The location of the last WAL byte + 1 flushed to disk in the standby.

Int64
The location of the last WAL byte + 1 applied in the standby.

Int64
The client's system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Byte1
If 1, the client requests the server to reply to this message immediately. This can be used to ping the server, to test if the connection is still healthy.

Hot Standby feedback message (F)

Byte1('h')
Identifies the message as a Hot Standby feedback message.
Int64
   The client’s system clock at the time of transmission, as microseconds since midnight on 2000-01-01.

Int32
   The standby’s current xmin. This may be 0, if the standby is sending notification that Hot Standby feedback will no longer be sent on this connection. Later non-zero messages may reinitiate the feedback mechanism.

Int32
   The standby’s current epoch.

START_REPLICATION SLOT slot_name LOGICAL "XXX/XXX" [ ( option_name [ option_value ] [, ...] ) ]
   Instructs server to start streaming WAL for logical replication, starting at WAL position "XXX/XXX". The server can reply with an error, for example if the requested section of WAL has already been recycled. On success, server responds with a CopyBothResponse message, and then starts to stream WAL to the frontend.

   The messages inside the CopyBothResponse messages are of the same format documented for START_REPLICATION ... PHYSICAL.

   The output plugin associated with the selected slot is used to process the output for streaming.

SLOT slot_name
   The name of the slot to stream changes from. This parameter is required, and must correspond to an existing logical replication slot created with CREATE_REPLICATION_SLOT in LOGICAL mode.

"XXX/XXX"
   The WAL position to begin streaming at.

option_name
   The name of an option passed to the slot’s logical decoding plugin.

option_value
   Optional value, in the form of a string constant, associated with the specified option.

DROP_REPLICATION_SLOT slot_name
   Drops a replication slot, freeing any reserved server-side resources. If the slot is currently in use by an active connection, this command fails.

   slot_name
   The name of the slot to drop.

BASE_BACKUP [ LABEL 'label' ] [ PROGRESS ] [ FAST ] [ WAL ] [ NOWAIT ] [ MAX_RATE rate ] [ TABLESPACE_MAP ]
   Instructs the server to start streaming a base backup. The system will automatically be put in backup mode before the backup is started, and taken out of it when the backup is complete. The
following options are accepted:

**LABEL 'label'**

Sets the label of the backup. If none is specified, a backup label of base backup will be used. The quoting rules for the label are the same as a standard SQL string with standard_conforming_strings turned on.

**PROGRESS**

Request information required to generate a progress report. This will send back an approximate size in the header of each tablespace, which can be used to calculate how far along the stream is done. This is calculated by enumerating all the file sizes once before the transfer is even started, and might as such have a negative impact on the performance. In particular, it might take longer before the first data is streamed. Since the database files can change during the backup, the size is only approximate and might both grow and shrink between the time of approximation and the sending of the actual files.

**FAST**

Request a fast checkpoint.

**WAL**

Include the necessary WAL segments in the backup. This will include all the files between start and stop backup in the pg_xlog directory of the base directory tar file.

**NOWAIT**

By default, the backup will wait until the last required WAL segment has been archived, or emit a warning if log archiving is not enabled. Specifying NOWAIT disables both the waiting and the warning, leaving the client responsible for ensuring the required log is available.

**MAX_RATE rate**

Limit (throttle) the maximum amount of data transferred from server to client per unit of time. The expected unit is kilobytes per second. If this option is specified, the value must either be equal to zero or it must fall within the range from 32 kB through 1 GB (inclusive). If zero is passed or the option is not specified, no restriction is imposed on the transfer.

**TABLESPACE_MAP**

Include information about symbolic links present in the directory pg_tblspc in a file named tablespace_map. The tablespace map file includes each symbolic link name as it exists in the directory pg_tblspc/ and the full path of that symbolic link.

When the backup is started, the server will first send two ordinary result sets, followed by one or more CopyResponse results.

The first ordinary result set contains the starting position of the backup, in a single row with two columns. The first column contains the start position given in XLogRecPtr format, and the second column contains the corresponding timeline ID.

The second ordinary result set has one row for each tablespace. The fields in this row are:

- **spcid(oid)**
  
  The OID of the tablespace, or null if it’s the base directory.

- **spclocation(text)**
  
  The full path of the tablespace directory, or null if it’s the base directory.
size (int8)

The approximate size of the tablespace, if progress report has been requested; otherwise it’s null.

After the second regular result set, one or more CopyResponse results will be sent, one for the main data directory and one for each additional tablespace other than pg_default and pg_global. The data in the CopyResponse results will be a tar format (following the “ustar interchange format” specified in the POSIX 1003.1-2008 standard) dump of the tablespace contents, except that the two trailing blocks of zeroes specified in the standard are omitted. After the tar data is complete, a final ordinary result set will be sent, containing the WAL end position of the backup, in the same format as the start position.

The tar archive for the data directory and each tablespace will contain all files in the directories, regardless of whether they are PostgreSQL files or other files added to the same directory. The only excluded files are:

- `postmaster.pid`
- `postmaster.opts`
- various temporary files created during the operation of the PostgreSQL server
- `pg_xlog` including subdirectories. If the backup is run with WAL files included, a synthesized version of `pg_xlog` will be included, but it will only contain the files necessary for the backup to work, not the rest of the contents.
- `pg_replslot` is copied as an empty directory.
- Files other than regular files and directories, such as symbolic links and special device files, are skipped. (Symbolic links in `pg_tblspc` are maintained.)

Owner, group, and file mode are set if the underlying file system on the server supports it.

51.4. Message Data Types

This section describes the base data types used in messages.

`Intn(i)`

An n-bit integer in network byte order (most significant byte first). If i is specified it is the exact value that will appear, otherwise the value is variable. Eg. Int16, Int32(42).

`Intn[k]`

An array of k n-bit integers, each in network byte order. The array length k is always determined by an earlier field in the message. Eg. Int16[M].

`String(s)`

A null-terminated string (C-style string). There is no specific length limitation on strings. If s is specified it is the exact value that will appear, otherwise the value is variable. Eg. String, String("user").

Note: There is no predefined limit on the length of a string that can be returned by the backend. Good coding strategy for a frontend is to use an expandable buffer so that anything that fits in memory can be accepted. If that’s not feasible, read the full string and discard trailing characters that don’t fit into your fixed-size buffer.
Byte\(n(c)\)

Exactly \(n\) bytes. If the field width \(n\) is not a constant, it is always determinable from an earlier field in the message. If \(c\) is specified it is the exact value. Eg. Byte2, Byte1(\"n\")

51.5. Message Formats

This section describes the detailed format of each message. Each is marked to indicate that it can be sent by a frontend (F), a backend (B), or both (F & B). Notice that although each message includes a byte count at the beginning, the message format is defined so that the message end can be found without reference to the byte count. This aids validity checking. (The CopyData message is an exception, because it forms part of a data stream; the contents of any individual CopyData message cannot be interpretable on their own.)

AuthenticationOk (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(0)
Specifies that the authentication was successful.

AuthenticationKerberosV5 (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(2)
Specifies that Kerberos V5 authentication is required.

AuthenticationCleartextPassword (B)

Byte1('R')
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(3)
Specifies that a clear-text password is required.

AuthenticationMD5Password (B)
Byte1(‘R’)
Identifies the message as an authentication request.
Int32(12)
Length of message contents in bytes, including self.
Int32(5)
Specifies that an MD5-encrypted password is required.
Byte4
The salt to use when encrypting the password.

AuthenticationSCMCredential (B)
Byte1(‘R’)
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(6)
Specifies that an SCM credentials message is required.

AuthenticationGSS (B)
Byte1(‘R’)
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Int32(7)
Specifies that GSSAPI authentication is required.

AuthenticationSSPI (B)
Byte1(‘R’)
Identifies the message as an authentication request.
Int32(8)
Length of message contents in bytes, including self.
Chapter 51. Frontend/Backend Protocol

Int32(9)

Specifies that SSPI authentication is required.

AuthenticationGSSContinue (B)

Byte1(‘R’)

Identifies the message as an authentication request.

Int32

Length of message contents in bytes, including self.

Int32(8)

Specifies that this message contains GSSAPI or SSPI data.

Byte

GSSAPI or SSPI authentication data.

BackendKeyData (B)

Byte1(‘K’)

Identifies the message as cancellation key data. The frontend must save these values if it wishes to be able to issue CancelRequest messages later.

Int32(12)

Length of message contents in bytes, including self.

Int32

The process ID of this backend.

Int32

The secret key of this backend.

Bind (F)

Byte1(‘B’)

Identifies the message as a Bind command.

Int32

Length of message contents in bytes, including self.

String

The name of the destination portal (an empty string selects the unnamed portal).

String

The name of the source prepared statement (an empty string selects the unnamed prepared statement).
The number of parameter format codes that follow (denoted $c$ below). This can be zero to indicate that there are no parameters or that the parameters all use the default format (text); or one, in which case the specified format code is applied to all parameters; or it can equal the actual number of parameters.

The parameter format codes. Each must presently be zero (text) or one (binary).

The number of parameter values that follow (possibly zero). This must match the number of parameters needed by the query.

Next, the following pair of fields appear for each parameter:

The length of the parameter value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL parameter value. No value bytes follow in the NULL case.

The value of the parameter, in the format indicated by the associated format code. $n$ is the above length.

After the last parameter, the following fields appear:

The number of result-column format codes that follow (denoted $r$ below). This can be zero to indicate that there are no result columns or that the result columns should all use the default format (text); or one, in which case the specified format code is applied to all result columns (if any); or it can equal the actual number of result columns of the query.

The result-column format codes. Each must presently be zero (text) or one (binary).

Identifies the message as a Bind-complete indicator.

Length of message contents in bytes, including self.

Identifies the message as a Cancel-complete indicator.

Length of message contents in bytes, including self.
Chapter 51. Frontend/Backend Protocol

Int32(80877102)

The cancel request code. The value is chosen to contain 1234 in the most significant 16 bits, and 5678 in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

Int32

The process ID of the target backend.

Int32

The secret key for the target backend.

Close (F)

Byte1('C')

Identifies the message as a Close command.

Int32

Length of message contents in bytes, including self.

Byte1

'S' to close a prepared statement; or 'P' to close a portal.

String

The name of the prepared statement or portal to close (an empty string selects the unnamed prepared statement or portal).

CloseComplete (B)

Byte1('3')

Identifies the message as a Close-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CommandComplete (B)

Byte1('C')

Identifies the message as a command-completed response.

Int32

Length of message contents in bytes, including self.

String

The command tag. This is usually a single word that identifies which SQL command was completed.

For an INSERT command, the tag is INSERT oid rows, where rows is the number of rows inserted. oid is the object ID of the inserted row if rows is 1 and the target table has OIDs; otherwise oid is 0.
Chapter 51. Frontend/Backend Protocol

For a DELETE command, the tag is DELETE rows where rows is the number of rows deleted.

For an UPDATE command, the tag is UPDATE rows where rows is the number of rows updated.

For a SELECT or CREATE TABLE AS command, the tag is SELECT rows where rows is the number of rows retrieved.

For a MOVE command, the tag is MOVE rows where rows is the number of rows the cursor’s position has been changed by.

For a FETCH command, the tag is FETCH rows where rows is the number of rows that have been retrieved from the cursor.

For a COPY command, the tag is COPY rows where rows is the number of rows copied. (Note: the row count appears only in PostgreSQL 8.2 and later.)

CopyData (F & B)

Byte1 (‘d’)

Identifies the message as COPY data.

Int32

Length of message contents in bytes, including self.

Byte

Data that forms part of a COPY data stream. Messages sent from the backend will always correspond to single data rows, but messages sent by frontends might divide the data stream arbitrarily.

CopyDone (F & B)

Byte1 (‘c’)

Identifies the message as a COPY-complete indicator.

Int32(4)

Length of message contents in bytes, including self.

CopyFail (F)

Byte1 (‘f’)

Identifies the message as a COPY-failure indicator.

Int32

Length of message contents in bytes, including self.

String

An error message to report as the cause of failure.
CopyInResponse (B)

Byte1(‘G’)
Identifies the message as a Start Copy In response. The frontend must now send copy-in data (if not prepared to do so, send a CopyFail message).

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall copy format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted N below).

Int16[N]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyOutResponse (B)

Byte1(‘H’)
Identifies the message as a Start Copy Out response. This message will be followed by copy-out data.

Int32
Length of message contents in bytes, including self.

Int8
0 indicates the overall copy format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted N below).

Int16[N]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

CopyBothResponse (B)

Byte1(‘W’)
Identifies the message as a Start Copy Both response. This message is used only for Streaming Replication.

Int32
Length of message contents in bytes, including self.
Chapter 51. Frontend/Backend Protocol

Int8
0 indicates the overall COPY format is textual (rows separated by newlines, columns separated by separator characters, etc). 1 indicates the overall copy format is binary (similar to DataRow format). See COPY for more information.

Int16
The number of columns in the data to be copied (denoted N below).

Int16[N]
The format codes to be used for each column. Each must presently be zero (text) or one (binary). All must be zero if the overall copy format is textual.

DataRow (B)

Byte1('D')
Identifies the message as a data row.

Int32
Length of message contents in bytes, including self.

Int16
The number of column values that follow (possibly zero).

Next, the following pair of fields appear for each column:

Int32
The length of the column value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL column value. No value bytes follow in the NULL case.

Byte
The value of the column, in the format indicated by the associated format code. n is the above length.

Describe (F)

Byte1('D')
Identifies the message as a Describe command.

Int32
Length of message contents in bytes, including self.

Byte1
's' to describe a prepared statement; or 'p' to describe a portal.

String
The name of the prepared statement or portal to describe (an empty string selects the unnamed prepared statement or portal).
Chapter 51. Frontend/Backend Protocol

EmptyQueryResponse (B)

Byte1(‘I’)
Identifies the message as a response to an empty query string. (This substitutes for CommandComplete.)

Int32(4)
Length of message contents in bytes, including self.

ErrorResponse (B)

Byte1(‘E’)
Identifies the message as an error.

Int32
Length of message contents in bytes, including self.
The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:

Byte1
A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 51.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
The field value.

Execute (F)

Byte1(‘E’)
Identifies the message as an Execute command.

Int32
Length of message contents in bytes, including self.

String
The name of the portal to execute (an empty string selects the unnamed portal).

Int32
Maximum number of rows to return, if portal contains a query that returns rows (ignored otherwise). Zero denotes “no limit”.

Flush (F)

Byte1(‘H’)
Identifies the message as a Flush command.
Chapter 51. Frontend/Backend Protocol

Int32(4)
Length of message contents in bytes, including self.

FunctionCall (F)

Byte1(‘F’)  
Identifies the message as a function call.

Int32  
Length of message contents in bytes, including self.

Int32  
Specifies the object ID of the function to call.

Int16  
The number of argument format codes that follow (denoted \( c \) below). This can be zero to indicate that there are no arguments or that the arguments all use the default format (text); or one, in which case the specified format code is applied to all arguments; or it can equal the actual number of arguments.

Int16[\( c \)]  
The argument format codes. Each must presently be zero (text) or one (binary).

Int16  
Specifies the number of arguments being supplied to the function.

Next, the following pair of fields appear for each argument:

Int32  
The length of the argument value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL argument value. No value bytes follow in the NULL case.

Byte\( n \)  
The value of the argument, in the format indicated by the associated format code. \( n \) is the above length.

After the last argument, the following field appears:

Int16  
The format code for the function result. Must presently be zero (text) or one (binary).

FunctionCallResponse (B)

Byte1(‘V’)  
Identifies the message as a function call result.

Int32  
Length of message contents in bytes, including self.
Chapter 51. Frontend/Backend Protocol

Int32
The length of the function result value, in bytes (this count does not include itself). Can be zero. As a special case, -1 indicates a NULL function result. No value bytes follow in the NULL case.

Byte n
The value of the function result, in the format indicated by the associated format code. n is the above length.

NegotiateProtocolVersion (B)

Byte1('v')
Identifies the message as a protocol version negotiation message.

Int32
Length of message contents in bytes, including self.

Int32
Newest minor protocol version supported by the server for the major protocol version requested by the client.

Int32
Number of protocol options not recognized by the server.

Then, for protocol option not recognized by the server, there is the following:

String
The option name.

NoData (B)

Byte1('n')
Identifies the message as a no-data indicator.

Int32(4)
Length of message contents in bytes, including self.

NoticeResponse (B)

Byte1('N')
Identifies the message as a notice.

Int32
Length of message contents in bytes, including self.

The message body consists of one or more identified fields, followed by a zero byte as a terminator. Fields can appear in any order. For each field there is the following:
Byte1
   A code identifying the field type; if zero, this is the message terminator and no string follows. The presently defined field types are listed in Section 51.6. Since more field types might be added in future, frontends should silently ignore fields of unrecognized type.

String
   The field value.

NotificationResponse (B)

Byte1('A')
   Identifies the message as a notification response.
Int32
   Length of message contents in bytes, including self.
Int32
   The process ID of the notifying backend process.
String
   The name of the channel that the notify has been raised on.
String
   The “payload” string passed from the notifying process.

ParameterDescription (B)

Byte1('t')
   Identifies the message as a parameter description.
Int32
   Length of message contents in bytes, including self.
Int16
   The number of parameters used by the statement (can be zero).

Then, for each parameter, there is the following:

Int32
   Specifies the object ID of the parameter data type.

ParameterStatus (B)

Byte1('S')
   Identifies the message as a run-time parameter status report.
Int32
   Length of message contents in bytes, including self.
String
The name of the run-time parameter being reported.
String
The current value of the parameter.

Parse (F)

Byte1(‘P’)
Identifies the message as a Parse command.
Int32
Length of message contents in bytes, including self.
String
The name of the destination prepared statement (an empty string selects the unnamed prepared statement).
String
The query string to be parsed.
Int16
The number of parameter data types specified (can be zero). Note that this is not an indication of the number of parameters that might appear in the query string, only the number that the frontend wants to prespecify types for.

Then, for each parameter, there is the following:

Int32
Specifies the object ID of the parameter data type. Placing a zero here is equivalent to leaving the type unspecified.

ParseComplete (B)

Byte1(‘1’)
Identifies the message as a Parse-complete indicator.
Int32(4)
Length of message contents in bytes, including self.

PasswordMessage (F)

Byte1(‘p’)
Identifies the message as a password response. Note that this is also used for GSSAPI and SSPI response messages (which is really a design error, since the contained data is not a null-terminated string in that case, but can be arbitrary binary data).
Int32
Length of message contents in bytes, including self.
String
    The password (encrypted, if requested).

PortalSuspended (B)

Byte1('s')
    Identifies the message as a portal-suspended indicator. Note this only appears if an Execute
    message's row-count limit was reached.
Int32(4)
    Length of message contents in bytes, including self.

Query (F)

Byte1('Q')
    Identifies the message as a simple query.
Int32
    Length of message contents in bytes, including self.
String
    The query string itself.

ReadyForQuery (B)

Byte1('Z')
    Identifies the message type. ReadyForQuery is sent whenever the backend is ready for a
    new query cycle.
Int32(5)
    Length of message contents in bytes, including self.
Byte1
    Current backend transaction status indicator. Possible values are 'I' if idle (not in a transac-
    tion block); 'T' if in a transaction block; or 'E' if in a failed transaction block (queries will
    be rejected until block is ended).

RowDescription (B)

Byte1('T')
    Identifies the message as a row description.
Int32
    Length of message contents in bytes, including self.
Chapter 51. Frontend/Backend Protocol

Int16
Specifies the number of fields in a row (can be zero).

Then, for each field, there is the following:

String
The field name.

Int32
If the field can be identified as a column of a specific table, the object ID of the table; otherwise zero.

Int16
If the field can be identified as a column of a specific table, the attribute number of the column; otherwise zero.

Int32
The object ID of the field’s data type.

Int16
The data type size (see \texttt{pg\_type.typlen}). Note that negative values denote variable-width types.

Int32
The type modifier (see \texttt{pg\_attribute.atttypmod}). The meaning of the modifier is type-specific.

Int16
The format code being used for the field. Currently will be zero (text) or one (binary). In a \texttt{RowDescription} returned from the statement variant of Describe, the format code is not yet known and will always be zero.

SSLRequest (F)

Int32\((8)\)
Length of message contents in bytes, including self.

Int32\((80877103)\)
The SSL request code. The value is chosen to contain \texttt{1234} in the most significant 16 bits, and \texttt{5679} in the least significant 16 bits. (To avoid confusion, this code must not be the same as any protocol version number.)

StartupMessage (F)

Int32
Length of message contents in bytes, including self.

Int32\((196608)\)
The protocol version number. The most significant 16 bits are the major version number (3 for the protocol described here). The least significant 16 bits are the minor version number (0 for the protocol described here).
The protocol version number is followed by one or more pairs of parameter name and value strings. A zero byte is required as a terminator after the last name/value pair. Parameters can appear in any order. user is required, others are optional. Each parameter is specified as:

String
The parameter name. Currently recognized names are:

user
The database user name to connect as. Required; there is no default.
database
The database to connect to. Defaults to the user name.
options
Command-line arguments for the backend. (This is deprecated in favor of setting individual run-time parameters.) Spaces within this string are considered to separate arguments, unless escaped with a backslash (\); write \ to represent a literal backslash.

In addition to the above, other parameters may be listed. Parameter names beginning with _pq_. are reserved for use as protocol extensions, while others are treated as run-time parameters to be set at backend start time. Such settings will be applied during backend start (after parsing the command-line arguments if any) and will act as session defaults.

String
The parameter value.

Sync (F)
Byte1('S')
Identifies the message as a Sync command.
Int32(4)
Length of message contents in bytes, including self.

Terminate (F)
Byte1('X')
Identifies the message as a termination.
Int32(4)
Length of message contents in bytes, including self.

51.6. Error and Notice Message Fields
This section describes the fields that can appear in ErrorResponse and NoticeResponse messages. Each field type has a single-byte identification token. Note that any given field type should appear at most once per message.
Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message), or a localized translation of one of these. Always present.

Severity: the field contents are ERROR, FATAL, or PANIC (in an error message), or WARNING, NOTICE, DEBUG, INFO, or LOG (in a notice message). This is identical to the S field except that the contents are never localized. This is present only in messages generated by PostgreSQL versions 9.6 and later.

Code: the SQLSTATE code for the error (see Appendix A). Not localizable. Always present.

Message: the primary human-readable error message. This should be accurate but terse (typically one line). Always present.

Detail: an optional secondary error message carrying more detail about the problem. Might run to multiple lines.

Hint: an optional suggestion what to do about the problem. This is intended to differ from Detail in that it offers advice (potentially inappropriate) rather than hard facts. Might run to multiple lines.

Position: the field value is a decimal ASCII integer, indicating an error cursor position as an index into the original query string. The first character has index 1, and positions are measured in characters not bytes.

Internal position: this is defined the same as the P field, but it is used when the cursor position refers to an internally generated command rather than the one submitted by the client. The q field will always appear when this field appears.

Internal query: the text of a failed internally-generated command. This could be, for example, a SQL query issued by a PL/pgSQL function.

Where: an indication of the context in which the error occurred. Presently this includes a call stack traceback of active procedural language functions and internally-generated queries. The trace is one entry per line, most recent first.

Schema name: if the error was associated with a specific database object, the name of the schema containing that object, if any.

Table name: if the error was associated with a specific table, the name of the table. (Refer to the schema name field for the name of the table’s schema.)
Column name: if the error was associated with a specific table column, the name of the column. (Refer to the schema and table name fields to identify the table.)

Data type name: if the error was associated with a specific data type, the name of the data type. (Refer to the schema name field for the name of the data type’s schema.)

Constraint name: if the error was associated with a specific constraint, the name of the constraint. Refer to fields listed above for the associated table or domain. (For this purpose, indexes are treated as constraints, even if they weren’t created with constraint syntax.)

File: the file name of the source-code location where the error was reported.

Line: the line number of the source-code location where the error was reported.

Routine: the name of the source-code routine reporting the error.

Note: The fields for schema name, table name, column name, data type name, and constraint name are supplied only for a limited number of error types; see Appendix A. Frontends should not assume that the presence of any of these fields guarantees the presence of another field. Core error sources observe the interrelationships noted above, but user-defined functions may use these fields in other ways. In the same vein, clients should not assume that these fields denote contemporary objects in the current database.

The client is responsible for formatting displayed information to meet its needs; in particular it should break long lines as needed. Newline characters appearing in the error message fields should be treated as paragraph breaks, not line breaks.

51.7. Summary of Changes since Protocol 2.0

This section provides a quick checklist of changes, for the benefit of developers trying to update existing client libraries to protocol 3.0.

The initial startup packet uses a flexible list-of-strings format instead of a fixed format. Notice that session default values for run-time parameters can now be specified directly in the startup packet. (Actually, you could do that before using the `options` field, but given the limited width of `options` and the lack of any way to quote whitespace in the values, it wasn’t a very safe technique.)

All messages now have a length count immediately following the message type byte (except for startup packets, which have no type byte). Also note that `PasswordMessage` now has a type byte.

`ErrorResponse` and `NoticeResponse` (‘E’ and ‘N’) messages now contain multiple fields, from which the client code can assemble an error message of the desired level of verbosity. Note that individual fields will typically not end with a newline, whereas the single string sent in the older protocol always did.

The `ReadyForQuery` (‘Z’) message includes a transaction status indicator.
The distinction between BinaryRow and DataRow message types is gone; the single DataRow message type serves for returning data in all formats. Note that the layout of DataRow has changed to make it easier to parse. Also, the representation of binary values has changed: it is no longer directly tied to the server’s internal representation.

There is a new “extended query” sub-protocol, which adds the frontend message types Parse, Bind, Execute, Describe, Close, Flush, and Sync, and the backend message types ParseComplete, BindComplete, PortalSuspended, ParameterDescription, NoData, and CloseComplete. Existing clients do not have to concern themselves with this sub-protocol, but making use of it might allow improvements in performance or functionality.

COPY data is now encapsulated into CopyData and CopyDone messages. There is a well-defined way to recover from errors during COPY. The special “\.” last line is not needed anymore, and is not sent during COPY OUT. (It is still recognized as a terminator during COPY IN, but its use is deprecated and will eventually be removed.) Binary COPY is supported. The CopyInResponse and CopyOutResponse messages include fields indicating the number of columns and the format of each column.

The layout of FunctionCall and FunctionCallResponse messages has changed. FunctionCall can now support passing NULL arguments to functions. It also can handle passing parameters and retrieving results in either text or binary format. There is no longer any reason to consider FunctionCall a potential security hole, since it does not offer direct access to internal server data representations.

The backend sends ParameterStatus (’S’) messages during connection startup for all parameters it considers interesting to the client library. Subsequently, a ParameterStatus message is sent whenever the active value changes for any of these parameters.

The RowDescription (’T’) message carries new table OID and column number fields for each column of the described row. It also shows the format code for each column.

The CursorResponse (’P’) message is no longer generated by the backend.

The NotificationResponse (’A’) message has an additional string field, which can carry a “payload” string passed from the NOTIFY event sender.

The EmptyQueryResponse (’I’) message used to include an empty string parameter; this has been removed.
Chapter 52. PostgreSQL Coding Conventions

52.1. Formatting

Source code formatting uses 4 column tab spacing, with tabs preserved (i.e., tabs are not expanded to spaces). Each logical indentation level is one additional tab stop.

Layout rules (brace positioning, etc) follow BSD conventions. In particular, curly braces for the controlled blocks of if, while, switch, etc go on their own lines.

Limit line lengths so that the code is readable in an 80-column window. (This doesn’t mean that you must never go past 80 columns. For instance, breaking a long error message string in arbitrary places just to keep the code within 80 columns is probably not a net gain in readability.)

Do not use C++ style comments (// comments). Strict ANSI C compilers do not accept them. For the same reason, do not use C++ extensions such as declaring new variables mid-block.

The preferred style for multi-line comment blocks is

```c
/*
 * comment text begins here
 * and continues here
 */
```

Note that comment blocks that begin in column 1 will be preserved as-is by pgindent, but it will reflow indented comment blocks as though they were plain text. If you want to preserve the line breaks in an indented block, add dashes like this:

```c
/----------
 * comment text begins here
 * and continues here
 *----------
 */
```

While submitted patches do not absolutely have to follow these formatting rules, it’s a good idea to do so. Your code will get run through pgindent before the next release, so there’s no point in making it look nice under some other set of formatting conventions. A good rule of thumb for patches is “make the new code look like the existing code around it”.

The `src/tools` directory contains sample settings files that can be used with the emacs, xemacs or vim editors to help ensure that they format code according to these conventions.

The text browsing tools more and less can be invoked as:

```bash
more -x4
less -x4
```

to make them show tabs appropriately.
52.2. Reporting Errors Within the Server

Error, warning, and log messages generated within the server code should be created using `ereport`, or its older cousin `elog`. The use of this function is complex enough to require some explanation.

There are two required elements for every message: a severity level (ranging from `DEBUG` to `PANIC`) and a primary message text. In addition there are optional elements, the most common of which is an error identifier code that follows the SQL spec’s SQLSTATE conventions. `ereport` itself is just a shell function, that exists mainly for the syntactic convenience of making message generation look like a function call in the C source code. The only parameter accepted directly by `ereport` is the severity level. The primary message text and any optional message elements are generated by calling auxiliary functions, such as `errmsg`, within the `ereport` call.

A typical call to `ereport` might look like this:

```c
ereport(ERROR,
    (errcode(ERRCODE_DIVISION_BY_ZERO),
     errmsg("division by zero")));
```

This specifies error severity level `ERROR` (a run-of-the-mill error). The `errcode` call specifies the SQLSTATE error code using a macro defined in `src/include/utils/errcodes.h`. The `errmsg` call provides the primary message text. Notice the extra set of parentheses surrounding the auxiliary function calls — these are annoying but syntactically necessary.

Here is a more complex example:

```c
ereport(ERROR,
    (errcode(ERRCODE_AMBIGUOUS_FUNCTION),
     errmsg("function %s is not unique",
      func_signature_string(funcname, nargs,
       NIL, actual_arg_types)),
     errhint("Unable to choose a best candidate function. "
      "You might need to add explicit typecasts.")));
```

This illustrates the use of format codes to embed run-time values into a message text. Also, an optional “hint” message is provided.

If the severity level is `ERROR` or higher, `ereport` aborts the execution of the user-defined function and does not return to the caller. If the severity level is lower than `ERROR`, `ereport` returns normally.

The available auxiliary routines for `ereport` are:

- `errcode` specifies the SQLSTATE error identifier code for the condition. If this routine is not called, the error identifier defaults to `ERRCODE_INTERNAL_ERROR` when the error severity level is `ERROR` or higher, `ERRCODE_WARNING` when the error level is `WARNING`, otherwise (for `NOTICE` and below) `ERRCODE_SUCCESSFUL_COMPLETION`. While these defaults are often convenient, always think whether they are appropriate before omitting the `errcode` call.

- `errmsg` specifies the primary error message text, and possibly run-time values to insert into it. Insertions are specified by `sprintf`-style format codes. In addition to the standard format codes accepted by `sprintf`, the format code `%m` can be used to insert the error message returned by `strerror` for the current value of `errno`. \(^1\) `%m` does not require any corresponding entry in the parameter list for `errmsg`. Note that the message string will be run through `gettext` for possible localization before format codes are processed.

---

1. That is, the value that was current when the `ereport` call was reached; changes of `errno` within the auxiliary reporting routines will not affect it. That would not be true if you were to write `strerror(errno)` explicitly in `errmsg`'s parameter list; accordingly, do not do so.
Chapter 52. PostgreSQL Coding Conventions

- `errmsg_internal` is the same as `errmsg`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for “cannot happen” cases that are probably not worth expending translation effort on.

- `errmsg_plural` is like `errmsg`, but with support for various plural forms of the message. `fmt_singular` is the English singular format, `fmt_plural` is the English plural format, `n` is the integer value that determines which plural form is needed, and the remaining arguments are formatted according to the selected format string. For more information see Section 53.2.2.

- `errdetail` supplies an optional “detail” message; this is to be used when there is additional information that seems inappropriate to put in the primary message. The message string is processed in just the same way as for `errmsg`.

- `errdetail_internal` is the same as `errdetail`, except that the message string will not be translated nor included in the internationalization message dictionary. This should be used for detail messages that are not worth expending translation effort on, for instance because they are too technical to be useful to most users.

- `errdetail_plural` is like `errdetail`, but with support for various plural forms of the message. For more information see Section 53.2.2.

- `errdetail_log` is the same as `errdetail` except that this string goes only to the server log, never to the client. If both `errdetail` (or one of its equivalents above) and `errdetail_log` are used then one string goes to the client and the other to the log. This is useful for error details that are too security-sensitive or too bulky to include in the report sent to the client.

- `errdetail_log_plural` is like `errdetail_log`, but with support for various plural forms of the message. For more information see Section 53.2.2.

- `errhint` supplies an optional “hint” message; this is to be used when offering suggestions about how to fix the problem, as opposed to factual details about what went wrong. The message string is processed in just the same way as for `errmsg`.

- `errcontext` is not normally called directly from an `ereport` message site; rather it is used in `error_context_stack` callback functions to provide information about the context in which an error occurred, such as the current location in a PL function. The message string is processed in just the same way as for `errmsg`. Unlike the other auxiliary functions, this can be called more than once per `ereport` call; the successive strings thus supplied are concatenated with separating newlines.

- `errposition` specifies the textual location of an error within a query string. Currently it is only useful for errors detected in the lexical and syntactic analysis phases of query processing.

- `errtable` specifies a relation whose name and schema name should be included as auxiliary fields in the error report.

- `errtablecol` specifies a column whose name, table name, and schema name should be included as auxiliary fields in the error report.

- `errtableconstraint` specifies a table constraint whose name, table name, and schema name should be included as auxiliary fields in the error report. Indexes should be considered to be constraints for this purpose, whether or not they have an associated `pg_constraint` entry. Be careful to pass the underlying heap relation, not the index itself, as `rel`. 
Chapter 52. PostgreSQL Coding Conventions

- `errdatatype(Oid datatypeOid)` specifies a data type whose name and schema name should be included as auxiliary fields in the error report.

- `errdomainconstraint(Oid datatypeOid, const char *conname)` specifies a domain constraint whose name, domain name, and schema name should be included as auxiliary fields in the error report.

- `errcode_for_file_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a file-access-related system call. It uses the saved `errno` to determine which error code to generate. Usually this should be used in combination with `%m` in the primary error message text.

- `errcode_for_socket_access()` is a convenience function that selects an appropriate SQLSTATE error identifier for a failure in a socket-related system call.

- `errhidestmt(bool hide_stmt)` can be called to specify suppression of the `STATEMENT:` portion of a message in the postmaster log. Generally this is appropriate if the message text includes the current statement already.

- `errhidecontext(bool hide_ctx)` can be called to specify suppression of the `CONTEXT:` portion of a message in the postmaster log. This should only be used for verbose debugging messages where the repeated inclusion of context would bloat the log volume too much.

Note: At most one of the functions `errtable`, `errtablecol`, `errtableconstraint`, `errdatatype`, or `errdomainconstraint` should be used in an `ereport` call. These functions exist to allow applications to extract the name of a database object associated with the error condition without having to examine the potentially-localized error message text. These functions should be used in error reports for which it's likely that applications would wish to have automatic error handling. As of PostgreSQL 9.3, complete coverage exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

There is an older function `elog` that is still heavily used. An `elog` call:

`elog(level, "format string", ...);`

is exactly equivalent to:

`ereport(level, (errmsg_internal("format string", ...)));`

Notice that the SQLSTATE error code is always defaulted, and the message string is not subject to translation. Therefore, `elog` should be used only for internal errors and low-level debug logging. Any message that is likely to be of interest to ordinary users should go through `ereport`. Nonetheless, there are enough internal “cannot happen” error checks in the system that `elog` is still widely used; it is preferred for those messages for its notational simplicity.

Advice about writing good error messages can be found in Section 52.3.

52.3. Error Message Style Guide

This style guide is offered in the hope of maintaining a consistent, user-friendly style throughout all the messages generated by PostgreSQL.
52.3.1. What Goes Where

The primary message should be short, factual, and avoid reference to implementation details such as specific function names. “Short” means “should fit on one line under normal conditions”. Use a detail message if needed to keep the primary message short, or if you feel a need to mention implementation details such as the particular system call that failed. Both primary and detail messages should be factual. Use a hint message for suggestions about what to do to fix the problem, especially if the suggestion might not always be applicable.

For example, instead of:

IpcMemoryCreate: shmget(key=%d, size=%u, 0%o) failed: %m
(plus a long addendum that is basically a hint)

write:

Primary:   could not create shared memory segment: %m
Detail:    Failed syscall was shmget(key=%d, size=%u, 0%o).
Hint:      the addendum

Rationale: keeping the primary message short helps keep it to the point, and lets clients lay out screen space on the assumption that one line is enough for error messages. Detail and hint messages can be relegated to a verbose mode, or perhaps a pop-up error-details window. Also, details and hints would normally be suppressed from the server log to save space. Reference to implementation details is best avoided since users aren’t expected to know the details.

52.3.2. Formatting

Don’t put any specific assumptions about formatting into the message texts. Expect clients and the server log to wrap lines to fit their own needs. In long messages, newline characters (\n) can be used to indicate suggested paragraph breaks. Don’t end a message with a newline. Don’t use tabs or other formatting characters. (In error context displays, newlines are automatically added to separate levels of context such as function calls.)

Rationale: Messages are not necessarily displayed on terminal-type displays. In GUI displays or browsers these formatting instructions are at best ignored.

52.3.3. Quotation Marks

English text should use double quotes when quoting is appropriate. Text in other languages should consistently use one kind of quotes that is consistent with publishing customs and computer output of other programs.

Rationale: The choice of double quotes over single quotes is somewhat arbitrary, but tends to be the preferred use. Some have suggested choosing the kind of quotes depending on the type of object according to SQL conventions (namely, strings single quoted, identifiers double quoted). But this is a language-internal technical issue that many users aren’t even familiar with, it won’t scale to other kinds of quoted terms, it doesn’t translate to other languages, and it’s pretty pointless, too.
52.3.4. Use of Quotes

Use quotes always to delimit file names, user-supplied identifiers, and other variables that might contain words. Do not use them to mark up variables that will not contain words (for example, operator names).

There are functions in the backend that will double-quote their own output at need (for example, `format_type_be()`). Do not put additional quotes around the output of such functions.

Rationale: Objects can have names that create ambiguity when embedded in a message. Be consistent about denoting where a plugged-in name starts and ends. But don’t clutter messages with unnecessary or duplicate quote marks.

52.3.5. Grammar and Punctuation

The rules are different for primary error messages and for detail/hint messages:

Primary error messages: Do not capitalize the first letter. Do not end a message with a period. Do not even think about ending a message with an exclamation point.

Detail and hint messages: Use complete sentences, and end each with a period. Capitalize the first word of sentences. Put two spaces after the period if another sentence follows (for English text; might be inappropriate in other languages).

Error context strings: Do not capitalize the first letter and do not end the string with a period. Context strings should normally not be complete sentences.

Rationale: Avoiding punctuation makes it easier for client applications to embed the message into a variety of grammatical contexts. Often, primary messages are not grammatically complete sentences anyway. (And if they’re long enough to be more than one sentence, they should be split into primary and detail parts.) However, detail and hint messages are longer and might need to include multiple sentences. For consistency, they should follow complete-sentence style even when there’s only one sentence.

52.3.6. Upper Case vs. Lower Case

Use lower case for message wording, including the first letter of a primary error message. Use upper case for SQL commands and key words if they appear in the message.

Rationale: It’s easier to make everything look more consistent this way, since some messages are complete sentences and some not.

52.3.7. Avoid Passive Voice

Use the active voice. Use complete sentences when there is an acting subject (“A could not do B”). Use telegram style without subject if the subject would be the program itself; do not use “I” for the program.

Rationale: The program is not human. Don’t pretend otherwise.
52.3.8. Present vs. Past Tense

Use past tense if an attempt to do something failed, but could perhaps succeed next time (perhaps after fixing some problem). Use present tense if the failure is certainly permanent.

There is a nontrivial semantic difference between sentences of the form:

could not open file "%s": %m

and:

cannot open file "%s"

The first one means that the attempt to open the file failed. The message should give a reason, such as “disk full” or “file doesn’t exist”. The past tense is appropriate because next time the disk might not be full anymore or the file in question might exist.

The second form indicates that the functionality of opening the named file does not exist at all in the program, or that it’s conceptually impossible. The present tense is appropriate because the condition will persist indefinitely.

Rationale: Granted, the average user will not be able to draw great conclusions merely from the tense of the message, but since the language provides us with a grammar we should use it correctly.

52.3.9. Type of the Object

When citing the name of an object, state what kind of object it is.

Rationale: Otherwise no one will know what “foo.bar.baz” refers to.

52.3.10. Brackets

Square brackets are only to be used (1) in command synopses to denote optional arguments, or (2) to denote an array subscript.

Rationale: Anything else does not correspond to widely-known customary usage and will confuse people.

52.3.11. Assembling Error Messages

When a message includes text that is generated elsewhere, embed it in this style:

could not open file %s: %m

Rationale: It would be difficult to account for all possible error codes to paste this into a single smooth sentence, so some sort of punctuation is needed. Putting the embedded text in parentheses has also been suggested, but it’s unnatural if the embedded text is likely to be the most important part of the message, as is often the case.
52.3.12. Reasons for Errors

Messages should always state the reason why an error occurred. For example:

BAD: could not open file %s
BETTER: could not open file %s (I/O failure)

If no reason is known you better fix the code.

52.3.13. Function Names

Don’t include the name of the reporting routine in the error text. We have other mechanisms for finding that out when needed, and for most users it’s not helpful information. If the error text doesn’t make as much sense without the function name, reword it.

BAD: pg_atoi: error in "z": cannot parse "z"
BETTER: invalid input syntax for integer: "z"

Avoid mentioning called function names, either; instead say what the code was trying to do:

BAD: open() failed: %m
BETTER: could not open file %s: %m

If it really seems necessary, mention the system call in the detail message. (In some cases, providing the actual values passed to the system call might be appropriate information for the detail message.)

Rationale: Users don’t know what all those functions do.

52.3.14. Tricky Words to Avoid

Unable. “Unable” is nearly the passive voice. Better use “cannot” or “could not”, as appropriate.

Bad. Error messages like “bad result” are really hard to interpret intelligently. It’s better to write why the result is “bad”, e.g., “invalid format”.

Illegal. “Illegal” stands for a violation of the law, the rest is “invalid”. Better yet, say why it’s invalid.

Unknown. Try to avoid “unknown”. Consider “error: unknown response”. If you don’t know what the response is, how do you know it’s erroneous? “Unrecognized” is often a better choice. Also, be sure to include the value being complained of.

BAD: unknown node type
BETTER: unrecognized node type: 42

Find vs. Exists. If the program uses a nontrivial algorithm to locate a resource (e.g., a path search) and that algorithm fails, it is fair to say that the program couldn’t “find” the resource. If, on the other hand, the expected location of the resource is known but the program cannot access it there then say that the resource doesn’t “exist”. Using “find” in this case sounds weak and confuses the issue.

May vs. Can vs. Might. “May” suggests permission (e.g., “You may borrow my rake.”), and has little use in documentation or error messages. “Can” suggests ability (e.g., “I can lift that log.”), and “might” suggests possibility (e.g., “It might rain today.”). Using the proper word clarifies meaning and assists translation.

Contractions. Avoid contractions, like “can’t”; use “cannot” instead.
52.3.15. Proper Spelling

Spell out words in full. For instance, avoid:

- spec
- stats
- parens
- auth
- xact

Rationale: This will improve consistency.

52.3.16. Localization

Keep in mind that error message texts need to be translated into other languages. Follow the guidelines in Section 53.2.2 to avoid making life difficult for translators.

52.4. Miscellaneous Coding Conventions

52.4.1. C Standard

Code in PostgreSQL should only rely on language features available in the C89 standard. That means a conforming C89 compiler has to be able to compile postgres, at least aside from a few platform dependent pieces. Features from later revision of the C standard or compiler specific features can be used, if a fallback is provided.

For example static inline and _StaticAssert() are currently used, even though they are from newer revisions of the C standard. If not available we respectively fall back to defining the functions without inline, and to using a C89 compatible replacement that performs the same checks, but emits rather cryptic messages.

52.4.2. Function-Like Macros and Inline Functions

Both, macros with arguments and static inline functions, may be used. The latter are preferable if there are multiple-evaluation hazards when written as a macro, as e.g. the case with

#define Max(x, y)   

or when the macro would be very long. In other cases it’s only possible to use macros, or at least easier. For example because expressions of various types need to be passed to the macro.

When the definition of an inline function references symbols (i.e. variables, functions) that are only available as part of the backend, the function may not be visible when included from frontend code.

#ifndef FRONTEND

static inline MemoryContext

#endif
Chapter 52. PostgreSQL Coding Conventions

MemoryContextSwitchTo(MemoryContext context)
{
    MemoryContext old = CurrentMemoryContext;

    CurrentMemoryContext = context;
    return old;
}
#endif /* FRONTEND */

In this example CurrentMemoryContext, which is only available in the backend, is referenced and
the function thus hidden with a #ifndef FRONTEND. This rule exists because some compilers emit
references to symbols contained in inline functions even if the function is not used.

52.4.3. Writing Signal Handlers

To be suitable to run inside a signal handler code has to be written very carefully. The fundamental
problem is that, unless blocked, a signal handler can interrupt code at any time. If code inside the
signal handler uses the same state as code outside chaos may ensue. As an example consider what
happens if a signal handler tries to acquire a lock that’s already held in the interrupted code.

Barring special arrangements code in signal handlers may only call async-signal safe functions (as
defined in POSIX) and access variables of type volatile sig_atomic_t. A few functions in
postgres are also deemed signal safe, importantly SetLatch().

In most cases signal handlers should do nothing more than note that a signal has arrived, and wake up
code running outside of the handler using a latch. An example of such a handler is the following:

static void
handle_sighup(SIGNAL_ARGS)
{
    int save_errno = errno;

    got_SIGHUP = true;
    SetLatch(MyLatch);

    errno = save_errno;
}

errno is saved and restored because SetLatch() might change it. If that were not done interrupted
code that’s currently inspecting errno might see the wrong value.
Chapter 53. Native Language Support

53.1. For the Translator

PostgreSQL programs (server and client) can issue their messages in your favorite language — if the messages have been translated. Creating and maintaining translated message sets needs the help of people who speak their own language well and want to contribute to the PostgreSQL effort. You do not have to be a programmer at all to do this. This section explains how to help.

53.1.1. Requirements

We won’t judge your language skills — this section is about software tools. Theoretically, you only need a text editor. But this is only in the unlikely event that you do not want to try out your translated messages. When you configure your source tree, be sure to use the `--enable-nls` option. This will also check for the `libintl` library and the `msgfmt` program, which all end users will need anyway. To try out your work, follow the applicable portions of the installation instructions.

If you want to start a new translation effort or want to do a message catalog merge (described later), you will need the programs `xgettext` and `msgmerge`, respectively, in a GNU-compatible implementation. Later, we will try to arrange it so that if you use a packaged source distribution, you won’t need `xgettext`. (If working from Git, you will still need it.) GNU Gettext 0.10.36 or later is currently recommended.

Your local gettext implementation should come with its own documentation. Some of that is probably duplicated in what follows, but for additional details you should look there.

53.1.2. Concepts

The pairs of original (English) messages and their (possibly) translated equivalents are kept in message catalogs, one for each program (although related programs can share a message catalog) and for each target language. There are two file formats for message catalogs: The first is the “PO” file (for Portable Object), which is a plain text file with special syntax that translators edit. The second is the “MO” file (for Machine Object), which is a binary file generated from the respective PO file and is used while the internationalized program is run. Translators do not deal with MO files; in fact hardly anyone does.

The extension of the message catalog file is no surprise either `.po` or `.mo`. The base name is either the name of the program it accompanies, or the language the file is for, depending on the situation. This is a bit confusing. Examples are `psql.po` (PO file for psql) or `fr.mo` (MO file in French).

The file format of the PO files is illustrated here:

```plaintext
# comment
msgid "original string"
msgstr "translated string"
msgid "more original"
```
The msgid’s are extracted from the program source. (They need not be, but this is the most common way.) The msgstr lines are initially empty and are filled in with useful strings by the translator. The strings can contain C-style escape characters and can be continued across lines as illustrated. (The next line must start at the beginning of the line.)

The # character introduces a comment. If whitespace immediately follows the # character, then this is a comment maintained by the translator. There can also be automatic comments, which have a non-whitespace character immediately following the #. These are maintained by the various tools that operate on the PO files and are intended to aid the translator.

#. automatic comment
#: filename.c:1023
#, flags, flags

The #. style comments are extracted from the source file where the message is used. Possibly the programmer has inserted information for the translator, such as about expected alignment. The #: comment indicates the exact location(s) where the message is used in the source. The translator need not look at the program source, but can if there is doubt about the correct translation. The #, comments contain flags that describe the message in some way. There are currently two flags: fuzzy is set if the message has possibly been outdated because of changes in the program source. The translator can then verify this and possibly remove the fuzzy flag. Note that fuzzy messages are not made available to the end user. The other flag is c-format, which indicates that the message is a printf-style format template. This means that the translation should also be a format string with the same number and type of placeholders. There are tools that can verify this, which key off the c-format flag.

### 53.1.3. Creating and Maintaining Message Catalogs

OK, so how does one create a “blank” message catalog? First, go into the directory that contains the program whose messages you want to translate. If there is a file nls.mk, then this program has been prepared for translation.

If there are already some .po files, then someone has already done some translation work. The files are named language.po, where language is the ISO 639-1 two-letter language code (in lower case)\(^1\), e.g., fr.po for French. If there is really a need for more than one translation effort per language then the files can also be named language_region.po where region is the ISO 3166-1 two-letter country code (in upper case)\(^2\), e.g., pt_BR.po for Portuguese in Brazil. If you find the language you wanted you can just start working on that file.

If you need to start a new translation effort, then first run the command:

```
make init-po
```

This will create a file programe.pot (.pot to distinguish it from PO files that are “in production”. The T stands for “template”.) Copy this file to language.po and edit it. To make it known that the new language is available, also edit the file nls.mk and add the language (or language and country) code to the line that looks like:

---

2. http://www.iso.org/iso/country_names_and_code_elements

---
AVAIL_LANGUAGES := de fr

(Other languages can appear, of course.)

As the underlying program or library changes, messages might be changed or added by the programmers. In this case you do not need to start from scratch. Instead, run the command:

make update-po

which will create a new blank message catalog file (the pot file you started with) and will merge it with the existing PO files. If the merge algorithm is not sure about a particular message it marks it “fuzzy” as explained above. The new PO file is saved with a .po.new extension.

53.1.4. Editing the PO Files

The PO files can be edited with a regular text editor. The translator should only change the area between the quotes after the msgstr directive, add comments, and alter the fuzzy flag. There is (unsurprisingly) a PO mode for Emacs, which I find quite useful.

The PO files need not be completely filled in. The software will automatically fall back to the original string if no translation (or an empty translation) is available. It is no problem to submit incomplete translations for inclusions in the source tree; that gives room for other people to pick up your work. However, you are encouraged to give priority to removing fuzzy entries after doing a merge. Remember that fuzzy entries will not be installed; they only serve as reference for what might be the right translation.

Here are some things to keep in mind while editing the translations:

- Make sure that if the original ends with a newline, the translation does, too. Similarly for tabs, etc.
- If the original is a printf format string, the translation also needs to be. The translation also needs to have the same format specifiers in the same order. Sometimes the natural rules of the language make this impossible or at least awkward. In that case you can modify the format specifiers like this:

  msgstr "Die Datei %2$s hat %1$u Zeichen."

  Then the first placeholder will actually use the second argument from the list. The digits need to follow the % immediately, before any other format manipulators. (This feature really exists in the printf family of functions. You might not have heard of it before because there is little use for it outside of message internationalization.)

- If the original string contains a linguistic mistake, report that (or fix it yourself in the program source) and translate normally. The corrected string can be merged in when the program sources have been updated. If the original string contains a factual mistake, report that (or fix it yourself) and do not translate it. Instead, you can mark the string with a comment in the PO file.

- Maintain the style and tone of the original string. Specifically, messages that are not sentences (cannot open file %s) should probably not start with a capital letter (if your language distinguishes letter case) or end with a period (if your language uses punctuation marks). It might help to read Section 52.3.

- If you don’t know what a message means, or if it is ambiguous, ask on the developers’ mailing list. Chances are that English speaking end users might also not understand it or find it ambiguous, so it’s best to improve the message.
53.2. For the Programmer

53.2.1. Mechanics

This section describes how to implement native language support in a program or library that is part of the PostgreSQL distribution. Currently, it only applies to C programs.

Adding NLS Support to a Program

1. Insert this code into the start-up sequence of the program:

```c
#ifdef ENABLE_NLS
#include <locale.h>
#endif
...

#ifdef ENABLE_NLS
setlocale(LC_ALL, "");
bindtextdomain("progname", LOCALEDIR);
textdomain("progname");
#endif
```

(The `progname` can actually be chosen freely.)

2. Wherever a message that is a candidate for translation is found, a call to `gettext()` needs to be inserted. E.g.:

```c
fprintf(stderr, "panic level %d\n", lvl);
```

would be changed to:

```c
fprintf(stderr, gettext("panic level %d\n"), lvl);
```

`(gettext is defined as a no-op if NLS support is not configured.)

This tends to add a lot of clutter. One common shortcut is to use:

```c
#define _(x) gettext(x)
```

Another solution is feasible if the program does much of its communication through one or a few functions, such as `ereport()` in the backend. Then you make this function call `gettext` internally on all input strings.

3. Add a file `nls.mk` in the directory with the program sources. This file will be read as a makefile. The following variable assignments need to be made here:

- **CATALOG_NAME**
  - The program name, as provided in the `textdomain()` call.

- **AVAIL_LANGUAGES**
  - List of provided translations — initially empty.

- **GETTEXT_FILES**
  - List of files that contain translatable strings, i.e., those marked with `gettext` or an alternative solution. Eventually, this will include nearly all source files of the program. If this list gets too long you can make the first “file” be a `+` and the second word be a file that contains one file name per line.
GETTEXT_TRIGGERS

The tools that generate message catalogs for the translators to work on need to know what function calls contain translatable strings. By default, only gettext() calls are known. If you used _ or other identifiers you need to list them here. If the translatable string is not the first argument, the item needs to be of the form func:2 (for the second argument). If you have a function that supports pluralized messages, the item should look like func:1,2 (identifying the singular and plural message arguments).

The build system will automatically take care of building and installing the message catalogs.

53.2.2. Message-writing Guidelines

Here are some guidelines for writing messages that are easily translatable.

- Do not construct sentences at run-time, like:
  
  printf("Files were %s\n", flag ? "copied" : "removed");

  The word order within the sentence might be different in other languages. Also, even if you remember to call gettext() on each fragment, the fragments might not translate well separately. It’s better to duplicate a little code so that each message to be translated is a coherent whole. Only numbers, file names, and such-like run-time variables should be inserted at run time into a message text.

- For similar reasons, this won’t work:
  
  printf("copied %d file%s", n, n!=1 ? "s" : "");

  because it assumes how the plural is formed. If you figured you could solve it like this:

  if (n==1)
      printf("copied 1 file");
  else
      printf("copied %d files", n):

  then be disappointed. Some languages have more than two forms, with some peculiar rules. It’s often best to design the message to avoid the issue altogether, for instance like this:

  printf("number of copied files: %d", n);

  If you really want to construct a properly pluralized message, there is support for this, but it’s a bit awkward. When generating a primary or detail error message in ereport(), you can write something like this:

  errmsg_plural("copied %d file",
               "copied %d files",
               n,
               n)

  The first argument is the format string appropriate for English singular form, the second is the format string appropriate for English plural form, and the third is the integer control value that determines which plural form to use. Subsequent arguments are formatted per the format string as usual. (Normally, the pluralization control value will also be one of the values to be formatted, so it has to be written twice.) In English it only matters whether n is 1 or not 1, but in other languages there can be many different plural forms. The translator sees the two English forms as a group and has the opportunity to supply multiple substitute strings, with the appropriate one being selected based on the run-time value of n.
If you need to pluralize a message that isn’t going directly to an `errmsg` or `errdetail` report, you have to use the underlying function `ngettext`. See the gettext documentation.

- If you want to communicate something to the translator, such as about how a message is intended to line up with other output, precede the occurrence of the string with a comment that starts with `translator`, e.g.:

```c
/* translator: This message is not what it seems to be. */
```

These comments are copied to the message catalog files so that the translators can see them.
Chapter 54. Writing A Procedural Language Handler

All calls to functions that are written in a language other than the current “version 1” interface for compiled languages (this includes functions in user-defined procedural languages, functions written in SQL, and functions using the version 0 compiled language interface) go through a call handler function for the specific language. It is the responsibility of the call handler to execute the function in a meaningful way, such as by interpreting the supplied source text. This chapter outlines how a new procedural language’s call handler can be written.

The call handler for a procedural language is a “normal” function that must be written in a compiled language such as C, using the version-1 interface, and registered with PostgreSQL as taking no arguments and returning the type language_handler. This special pseudotype identifies the function as a call handler and prevents it from being called directly in SQL commands. For more details on C language calling conventions and dynamic loading, see Section 36.9.

The call handler is called in the same way as any other function: It receives a pointer to a FunctionCallInfoData struct containing argument values and information about the called function, and it is expected to return a Datum result (and possibly set the isnull field of the FunctionCallInfoData structure, if it wishes to return an SQL null result). The difference between a call handler and an ordinary callee function is that the flinfo->fn_oid field of the FunctionCallInfoData structure will contain the OID of the actual function to be called, not of the call handler itself. The call handler must use this field to determine which function to execute. Also, the passed argument list has been set up according to the declaration of the target function, not of the call handler.

It’s up to the call handler to fetch the entry of the function from the pg_proc system catalog and to analyze the argument and return types of the called function. The AS clause from the CREATE FUNCTION command for the function will be found in the prosrc column of the pg_proc row. This is commonly source text in the procedural language, but in theory it could be something else, such as a path name to a file, or anything else that tells the call handler what to do in detail.

Often, the same function is called many times per SQL statement. A call handler can avoid repeated lookups of information about the called function by using the flinfo->fn_extra field. This will initially be NULL, but can be set by the call handler to point at information about the called function. On subsequent calls, if flinfo->fn_extra is already non-NULL then it can be used and the information lookup step skipped. The call handler must make sure that flinfo->fn_extra is made to point at memory that will live at least until the end of the current query, since an FmgrInfo data structure could be kept that long. One way to do this is to allocate the extra data in the memory context specified by flinfo->fn_mcxt; such data will normally have the same lifespan as the FmgrInfo itself. But the handler could also choose to use a longer-lived memory context so that it can cache function definition information across queries.

When a procedural-language function is invoked as a trigger, no arguments are passed in the usual way, but the FunctionCallInfoData's context field points at a TriggerData structure, rather than being NULL as it is in a plain function call. A language handler should provide mechanisms for procedural-language functions to get at the trigger information.

This is a template for a procedural-language handler written in C:

#include "postgres.h"
Chapter 54. Writing A Procedural Language Handler

```
#include "executor/spi.h"
#include "commands/trigger.h"
#include "fmgr.h"
#include "access/heapam.h"
#include "utils/syscache.h"
#include "catalog/pg_proc.h"
#include "catalog/pg_type.h"

#ifdef PG_MODULE_MAGIC
PG_MODULE_MAGIC;
#endif

PG_FUNCTION_INFO_V1(plsample_call_handler);

Datum
plsample_call_handler(PG_FUNCTION_ARGS)
{
    Datum retval;
    if (CALLED_AS_TRIGGER(fcinfo))
    {
        /*
         * Called as a trigger procedure
         */
        TriggerData *trigdata = (TriggerData *) fcinfo->context;
        retval = ...
    }
    else
    {
        /*
         * Called as a function
         */
        retval = ...
    }
    return retval;
}

Only a few thousand lines of code have to be added instead of the dots to complete the call handler.

After having compiled the handler function into a loadable module (see Section 36.9.6), the following
commands then register the sample procedural language:

CREATE FUNCTION plsample_call_handler() RETURNS language_handler
    AS 'filename'
    LANGUAGE C;
CREATE LANGUAGE plsample
    HANDLER plsample_call_handler;

Although providing a call handler is sufficient to create a minimal procedural language, there are two
other functions that can optionally be provided to make the language more convenient to use. These
are a validator and an inline handler. A validator can be provided to allow language-specific checking
to be done during CREATE FUNCTION. An inline handler can be provided to allow the language to
support anonymous code blocks executed via the DO command.
If a validator is provided by a procedural language, it must be declared as a function taking a single parameter of type `oid`. The validator’s result is ignored, so it is customarily declared to return `void`. The validator will be called at the end of a `CREATE FUNCTION` command that has created or updated a function written in the procedural language. The passed-in OID is the OID of the function’s `pg_proc` row. The validator must fetch this row in the usual way, and do whatever checking is appropriate. First, call `CheckFunctionValidatorAccess()` to diagnose explicit calls to the validator that the user could not achieve through `CREATE FUNCTION`. Typical checks then include verifying that the function’s argument and result types are supported by the language, and that the function’s body is syntactically correct in the language. If the validator finds the function to be okay, it should just return. If it finds an error, it should report that via the normal `ereport()` error reporting mechanism. Throwing an error will force a transaction rollback and thus prevent the incorrect function definition from being committed.

Validator functions should typically honor the `check_function_bodies` parameter: if it is turned off then any expensive or context-sensitive checking should be skipped. If the language provides for code execution at compilation time, the validator must suppress checks that would induce such execution. In particular, this parameter is turned off by `pg_dump` so that it can load procedural language functions without worrying about side effects or dependencies of the function bodies on other database objects. (Because of this requirement, the call handler should avoid assuming that the validator has fully checked the function. The point of having a validator is not to let the call handler omit checks, but to notify the user immediately if there are obvious errors in a `CREATE FUNCTION` command.) While the choice of exactly what to check is mostly left to the discretion of the validator function, note that the core `CREATE FUNCTION` code only executes `SET` clauses attached to a function when `check_function_bodies` is on. Therefore, checks whose results might be affected by GUC parameters definitely should be skipped when `check_function_bodies` is off, to avoid false failures when reloading a dump.

If an inline handler is provided by a procedural language, it must be declared as a function taking a single parameter of type `internal`. The inline handler’s result is ignored, so it is customarily declared to return `void`. The inline handler will be called when a `DO` statement is executed specifying the procedural language. The parameter actually passed is a pointer to an `InlineCodeBlock` struct, which contains information about the `DO` statement’s parameters, in particular the text of the anonymous code block to be executed. The inline handler should execute this code and return.

It’s recommended that you wrap all these function declarations, as well as the `CREATE LANGUAGE` command itself, into an `extension` so that a simple `CREATE EXTENSION` command is sufficient to install the language. See Section 36.15 for information about writing extensions.

The procedural languages included in the standard distribution are good references when trying to write your own language handler. Look into the `src/pl` subdirectory of the source tree. The `CREATE LANGUAGE` reference page also has some useful details.
Chapter 55. Writing A Foreign Data Wrapper

All operations on a foreign table are handled through its foreign data wrapper, which consists of a set of functions that the core server calls. The foreign data wrapper is responsible for fetching data from the remote data source and returning it to the PostgreSQL executor. If updating foreign tables is to be supported, the wrapper must handle that, too. This chapter outlines how to write a new foreign data wrapper.

The foreign data wrappers included in the standard distribution are good references when trying to write your own. Look into the contrib subdirectory of the source tree. The CREATE FOREIGN DATA WRAPPER reference page also has some useful details.

Note: The SQL standard specifies an interface for writing foreign data wrappers. However, PostgreSQL does not implement that API, because the effort to accommodate it into PostgreSQL would be large, and the standard API hasn’t gained wide adoption anyway.

55.1. Foreign Data Wrapper Functions

The FDW author needs to implement a handler function, and optionally a validator function. Both functions must be written in a compiled language such as C, using the version-1 interface. For details on C language calling conventions and dynamic loading, see Section 36.9.

The handler function simply returns a struct of function pointers to callback functions that will be called by the planner, executor, and various maintenance commands. Most of the effort in writing an FDW is in implementing these callback functions. The handler function must be registered with PostgreSQL as taking no arguments and returning the special pseudo-type fdw_handler. The callback functions are plain C functions and are not visible or callable at the SQL level. The callback functions are described in Section 55.2.

The validator function is responsible for validating options given in CREATE and ALTER commands for its foreign data wrapper, as well as foreign servers, user mappings, and foreign tables using the wrapper. The validator function must be registered as taking two arguments, a text array containing the options to be validated, and an OID representing the type of object the options are associated with (in the form of the OID of the system catalog the object would be stored in, either ForeignDataWrapperRelationId, ForeignServerRelationId, UserMappingRelationId, or ForeignTableRelationId). If no validator function is supplied, options are not checked at object creation time or object alteration time.

55.2. Foreign Data Wrapper Callback Routines

The FDW handler function returns a palloc’d FdwRoutine struct containing pointers to the callback functions described below. The scan-related functions are required, the rest are optional.

The FdwRoutine struct type is declared in src/include/foreign/fdwapi.h, which see for additional details.
Chapter 55. Writing A Foreign Data Wrapper

55.2.1. FDW Routines For Scanning Foreign Tables

void
GetForeignRelSize (PlannerInfo *root,
                    RelOptInfo *baserel,
                    Oid foreigntableid);

Obtain relation size estimates for a foreign table. This is called at the beginning of planning for a query that scans a foreign table. root is the planner’s global information about the query; baserel is the planner’s information about this table; and foreigntableid is the pg_class OID of the foreign table. (foreigntableid could be obtained from the planner data structures, but it’s passed explicitly to save effort.)

This function should update baserel->rows to be the expected number of rows returned by the table scan, after accounting for the filtering done by the restriction quals. The initial value of baserel->rows is just a constant default estimate, which should be replaced if at all possible. The function may also choose to update baserel->width if it can compute a better estimate of the average result row width.

See Section 55.4 for additional information.

void
GetForeignPaths (PlannerInfo *root,
                 RelOptInfo *baserel,
                 Oid foreigntableid);

Create possible access paths for a scan on a foreign table. This is called during query planning. The parameters are the same as for GetForeignRelSize, which has already been called.

This function must generate at least one access path (ForeignPath node) for a scan on the foreign table and must call add_path to add each such path to baserel->pathlist. It’s recommended to use create_foreignscan_path to build the ForeignPath nodes. The function can generate multiple access paths, e.g., a path which has valid pathkeys to represent a pre-sorted result. Each access path must contain cost estimates, and can contain any FDW-private information that is needed to identify the specific scan method intended.

See Section 55.4 for additional information.

ForeignScan *
GetForeignPlan (PlannerInfo *root,
                RelOptInfo *baserel,
                Oid foreigntableid,
                ForeignPath *best_path,
                List *tlist,
                List *scan_clauses,
                Plan *outer_plan);

Create a ForeignScan plan node from the selected foreign access path. This is called at the end of query planning. The parameters are as for GetForeignRelSize, plus the selected ForeignPath (previously produced by GetForeignPaths, GetForeignJoinPaths, or GetForeignUpperPaths), the target list to be emitted by the plan node, the restriction clauses to be enforced by the plan node, and the outer subplan of the ForeignScan, which is used for rechecks performed by RecheckForeignScan. (If the path is for a join rather than a base relation, foreigntableid is InvalidOid.)
This function must create and return a `ForeignScan` plan node; it’s recommended to use `make_foreignscan` to build the `ForeignScan` node.

See Section 55.4 for additional information.

```c
void
BeginForeignScan (ForeignScanState *node, int eflags);
```

Begin executing a foreign scan. This is called during executor startup. It should perform any initialization needed before the scan can start, but not start executing the actual scan (that should be done upon the first call to `IterateForeignScan`). The `ForeignScanState` node has already been created, but its `fdw_state` field is still NULL. Information about the table to scan is accessible through the `ForeignScanState` node (in particular, from the underlying `ForeignScan` plan node, which contains any FDW-private information provided by `GetForeignPlan`). `eflags` contains flag bits describing the executor’s operating mode for this plan node.

Note that when `(eflags & EXEC_FLAG_EXPLAIN_ONLY)` is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for `ExplainForeignScan` and `EndForeignScan`.

```c
TupleTableSlot *
IterateForeignScan (ForeignScanState *node);
```

Fetch one row from the foreign source, returning it in a tuple table slot (the node’s `ScanTupleSlot` should be used for this purpose). Return NULL if no more rows are available. The tuple table slot infrastructure allows either a physical or virtual tuple to be returned; in most cases the latter choice is preferable from a performance standpoint. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in `BeginForeignScan` if you need longer-lived storage, or use the `es_query_cxt` of the node’s `EState`.

The rows returned must match the `fdw_scan_tlist` target list if one was supplied, otherwise they must match the row type of the foreign table being scanned. If you choose to optimize away fetching columns that are not needed, you should insert nulls in those column positions, or else generate a `fdw_scan_tlist` list with those columns omitted.

Note that PostgreSQL’s executor doesn’t care whether the rows returned violate any constraints that were defined on the foreign table — but the planner does care, and may optimize queries incorrectly if there are rows visible in the foreign table that do not satisfy a declared constraint. If a constraint is violated when the user has declared that the constraint should hold true, it may be appropriate to raise an error (just as you would need to do in the case of a data type mismatch).

```c
void
ReScanForeignScan (ForeignScanState *node);
```

Restart the scan from the beginning. Note that any parameters the scan depends on may have changed value, so the new scan does not necessarily return exactly the same rows.

```c
void
EndForeignScan (ForeignScanState *node);
```

End the scan and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.
55.2.2. FDW Routines For Scanning Foreign Joins

If an FDW supports performing foreign joins remotely (rather than by fetching both tables’ data and doing the join locally), it should provide this callback function:

```c
void GetForeignJoinPaths (PlannerInfo *root, 
    RelOptInfo *joinrel, 
    RelOptInfo *outerrel, 
    RelOptInfo *innerrel, 
    JoinType jointype, 
    JoinPathExtraData *extra);
```

Create possible access paths for a join of two (or more) foreign tables that all belong to the same foreign server. This optional function is called during query planning. As with GetForeignPaths, this function should generate ForeignPath path(s) for the supplied joinrel, and call add_path to add these paths to the set of paths considered for the join. But unlike GetForeignPaths, it is not necessary that this function succeed in creating at least one path, since paths involving local joining are always possible.

Note that this function will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the FDW to minimize duplicated work.

If a ForeignPath path is chosen for the join, it will represent the entire join process; paths generated for the component tables and subsidiary joins will not be used. Subsequent processing of the join path proceeds much as it does for a path scanning a single foreign table. One difference is that the scanrelid of the resulting ForeignScan plan node should be set to zero, since there is no single relation that it represents; instead, the fs_relids field of the ForeignScan node represents the set of relations that were joined. (The latter field is set up automatically by the core planner code, and need not be filled by the FDW.) Another difference is that, because the column list for a remote join cannot be found from the system catalogs, the FDW must fill fdw_scan_tlist with an appropriate list of TargetEntry nodes, representing the set of columns it will supply at run time in the tuples it returns.

See Section 55.4 for additional information.

55.2.3. FDW Routines For Planning Post-Scan/Join Processing

If an FDW supports performing remote post-scan/join processing, such as remote aggregation, it should provide this callback function:

```c
void GetForeignUpperPaths (PlannerInfo *root, 
    UpperRelationKind stage, 
    RelOptInfo *input_rel, 
    RelOptInfo *output_rel);
```

Create possible access paths for upper relation processing, which is the planner’s term for all post-scan/join query processing, such as aggregation, window functions, sorting, and table updates. This optional function is called during query planning. Currently, it is called only if all base relation(s) involved in the query belong to the same FDW. This function should generate ForeignPath path(s) for any post-scan/join processing that the FDW knows how to perform remotely, and call add_path to add these paths to the indicated upper relation. As with GetForeignJoinPaths, it is not necessary
that this function succeed in creating any paths, since paths involving local processing are always possible.

The `stage` parameter identifies which post-scan/join step is currently being considered. `output_rel` is the upper relation that should receive paths representing computation of this step, and `input_rel` is the relation representing the input to this step. (Note that `ForeignPath` paths added to `output_rel` would typically not have any direct dependency on paths of the `input_rel`, since their processing is expected to be done externally. However, examining paths previously generated for the previous processing step can be useful to avoid redundant planning work.)

See Section 55.4 for additional information.

### 55.2.4. FDW Routines For Updating Foreign Tables

If an FDW supports writable foreign tables, it should provide some or all of the following callback functions depending on the needs and capabilities of the FDW:

```c
void AddForeignUpdateTargets (Query *parsetree,
                             RangeTblEntry *target_rte,
                             Relation target_relation);
```

**UPDATE** and **DELETE** operations are performed against rows previously fetched by the table-scanning functions. The FDW may need extra information, such as a row ID or the values of primary-key columns, to ensure that it can identify the exact row to update or delete. To support that, this function can add extra hidden, or “junk”, target columns to the list of columns that are to be retrieved from the foreign table during an **UPDATE** or **DELETE**.

To do that, add `TargetEntry` items to `parsetree->targetList`, containing expressions for the extra values to be fetched. Each such entry must be marked `resjunk = true`, and must have a distinct `resname` that will identify it at execution time. Avoid using names matching `ctidN`, `wholerow`, or `wholerown`, as the core system can generate junk columns of these names. If the extra expressions are more complex than simple Vars, they must be run through `eval_const_expressions` before adding them to the `targetlist`.

Although this function is called during planning, the information provided is a bit different from that available to other planning routines. `parsetree` is the parse tree for the **UPDATE** or **DELETE** command, while `target_rte` and `target_relation` describe the target foreign table.

If the `AddForeignUpdateTargets` pointer is set to `NULL`, no extra target expressions are added. (This will make it impossible to implement **DELETE** operations, though **UPDATE** may still be feasible if the FDW relies on an unchanging primary key to identify rows.)

```c
List * PlanForeignModify (PlannerInfo *root,
                         ModifyTable *plan,
                         Index resultRelation,
                         int subplan_index);
```

Perform any additional planning actions needed for an insert, update, or delete on a foreign table. This function generates the FDW-private information that will be attached to the `ModifyTable` plan node that performs the update action. This private information must have the form of a `List`, and will be delivered to `BeginForeignModify` during the execution stage.
root is the planner’s global information about the query. plan is the ModifyTable plan node, which is complete except for the fdwPrivLists field. resultRelation identifies the target foreign table by its range table index. subplan_index identifies which target of the ModifyTable plan node this is, counting from zero; use this if you want to index into plan->plans or other substructure of the plan node.

See Section 55.4 for additional information.

If the PlanForeignModify pointer is set to NULL, no additional plan-time actions are taken, and the fdw_private list delivered to BeginForeignModify will be NIL.

```c
void BeginForeignModify (ModifyTableState *mtstate,
                        ResultRelInfo *rinfo,
                        List *fdw_private,
                        int subplan_index,
                        int eflags);
```

Begin executing a foreign table modification operation. This routine is called during executor startup. It should perform any initialization needed prior to the actual table modifications. Subsequently, ExecForeignInsert, ExecForeignUpdate or ExecForeignDelete will be called for each tuple to be inserted, updated, or deleted.

mtstate is the overall state of the ModifyTable plan node being executed; global data about the plan and execution state is available via this structure. rinfo is the ResultRelInfo struct describing the target foreign table. (The ri_FdwState field of ResultRelInfo is available for the FDW to store any private state it needs for this operation.) fdw_private contains the private data generated by PlanForeignModify, if any. subplan_index identifies which target of the ModifyTable plan node this is. eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainForeignModify and EndForeignModify.

If the BeginForeignModify pointer is set to NULL, no action is taken during executor startup.

```c
TupleTableSlot * ExecForeignInsert (EState *estate,
                        ResultRelInfo *rinfo,
                        TupleTableSlot *slot,
                        TupleTableSlot *planSlot);
```

Insert one tuple into the foreign table. estate is global execution state for the query. rinfo is the ResultRelInfo struct describing the target foreign table. slot contains the tuple to be inserted; it will match the row-type definition of the foreign table. planSlot contains the tuple that was generated by the ModifyTable plan node’s subplan; it differs from slot in possibly containing additional “junk” columns. (The planSlot is typically of little interest for INSERT cases, but is provided for completeness.)

The return value is either a slot containing the data that was actually inserted (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually inserted (again, typically as a result of triggers). The passed-in slot can be re-used for this purpose.

The data in the returned slot is used only if the INSERT query has a RETURNING clause or the foreign table has an AFTER ROW trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the RETURNING clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.
Chapter 55. Writing A Foreign Data Wrapper

If the `ExecForeignInsert` pointer is set to NULL, attempts to insert into the foreign table will fail with an error message.

 TupleTableSlot *
 ExecForeignUpdate (EState *estate,
            ResultRelInfo *rinfo,
            TupleTableSlot *slot,
            TupleTableSlot *planSlot);

Update one tuple in the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains the new data for the tuple; it will match the row-type definition of the foreign table. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; it differs from `slot` in possibly containing additional “junk” columns. In particular, any junk columns that were requested by `AddForeignUpdateTargets` will be available from this slot.

The return value is either a slot containing the row as it was actually updated (this might differ from the data supplied, for example as a result of trigger actions), or NULL if no row was actually updated (again, typically as a result of triggers). The passed-in `slot` can be re-used for this purpose.

The data in the returned slot is used only if the `UPDATE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the `ExecForeignUpdate` pointer is set to NULL, attempts to update the foreign table will fail with an error message.

 TupleTableSlot *
 ExecForeignDelete (EState *estate,
            ResultRelInfo *rinfo,
            TupleTableSlot *slot,
            TupleTableSlot *planSlot);

Delete one tuple from the foreign table. `estate` is global execution state for the query. `rinfo` is the `ResultRelInfo` struct describing the target foreign table. `slot` contains nothing useful upon call, but can be used to hold the returned tuple. `planSlot` contains the tuple that was generated by the `ModifyTable` plan node's subplan; in particular, it will carry any junk columns that were requested by `AddForeignUpdateTargets`. The junk column(s) must be used to identify the tuple to be deleted.

The return value is either a slot containing the row that was deleted, or NULL if no row was deleted (typically as a result of triggers). The passed-in `slot` can be used to hold the tuple to be returned.

The data in the returned slot is used only if the `DELETE` query has a `RETURNING` clause or the foreign table has an `AFTER ROW` trigger. Triggers require all columns, but the FDW could choose to optimize away returning some or all columns depending on the contents of the `RETURNING` clause. Regardless, some slot must be returned to indicate success, or the query’s reported row count will be wrong.

If the `ExecForeignDelete` pointer is set to NULL, attempts to delete from the foreign table will fail with an error message.

 void
 EndForeignModify (EState *estate,
            ResultRelInfo *rinfo);
End the table update and release resources. It is normally not important to release palloc’d memory, but for example open files and connections to remote servers should be cleaned up.

If the `EndForeignModify` pointer is set to `NULL`, no action is taken during executor shutdown.

```c
int IsForeignRelUpdatable (Relation rel);
```

Report which update operations the specified foreign table supports. The return value should be a bit mask of rule event numbers indicating which operations are supported by the foreign table, using the `CmdType` enumeration; that is, `(1 << CMD_UPDATE) = 4` for `UPDATE`, `(1 << CMD_INSERT) = 8` for `INSERT`, and `(1 << CMD_DELETE) = 16` for `DELETE`.

If the `IsForeignRelUpdatable` pointer is set to `NULL`, foreign tables are assumed to be insertable, updatable, or deletable if the FDW provides `ExecForeignInsert`, `ExecForeignUpdate`, or `ExecForeignDelete` respectively. This function is only needed if the FDW supports some tables that are updatable and some that are not. (Even then, it's permissible to throw an error in the execution routine instead of checking in this function. However, this function is used to determine updatability for display in the `information_schema` views.)

Some inserts, updates, and deletes to foreign tables can be optimized by implementing an alternative set of interfaces. The ordinary interfaces for inserts, updates, and deletes fetch rows from the remote server and then modify those rows one at a time. In some cases, this row-by-row approach is necessary, but it can be inefficient. If it is possible for the foreign server to determine which rows should be modified without actually retrieving them, and if there are no local triggers which would affect the operation, then it is possible to arrange things so that the entire operation is performed on the remote server. The interfaces described below make this possible.

```c
bool PlanDirectModify (PlannerInfo *root,
                     ModifyTable *plan,
                     Index resultRelation,
                     int subplan_index);
```

Decide whether it is safe to execute a direct modification on the remote server. If so, return `true` after performing planning actions needed for that. Otherwise, return `false`. This optional function is called during query planning. If this function succeeds, `BeginDirectModify`, `IterateDirectModify` and `EndDirectModify` will be called at the execution stage, instead. Otherwise, the table modification will be executed using the table-updating functions described above. The parameters are the same as for `PlanForeignModify`.

To execute the direct modification on the remote server, this function must rewrite the target subplan with a `ForeignScan` plan node that executes the direct modification on the remote server. The `operation` field of the `ForeignScan` must be set to the `CmdType` enumeration appropriately; that is, `CMD_UPDATE` for `UPDATE`, `CMD_INSERT` for `INSERT`, and `CMD_DELETE` for `DELETE`.

See Section 55.4 for additional information.

If the `PlanDirectModify` pointer is set to `NULL`, no attempts to execute a direct modification on the remote server are taken.

```c
void BeginDirectModify (ForeignScanState *node,
                        int eflags);
```
Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to IterateDirectModify). The ForeignScanState node has already been created, but its fdw_state field is still NULL. Information about the table to modify is accessible through the ForeignScanState node (in particular, from the underlying ForeignScan plan node, which contains any FDW-private information provided by PlanDirectModify). eflags contains flag bits describing the executor’s operating mode for this plan node.

Prepare to execute a direct modification on the remote server. This is called during executor startup. It should perform any initialization needed prior to the direct modification (that should be done upon the first call to IterateDirectModify). The ForeignScanState node has already been created, but its fdw_state field is still NULL. Information about the table to modify is accessible through the ForeignScanState node (in particular, from the underlying ForeignScan plan node, which contains any FDW-private information provided by PlanDirectModify). eflags contains flag bits describing the executor’s operating mode for this plan node.

Note that when (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, this function should not perform any externally-visible actions; it should only do the minimum required to make the node state valid for ExplainDirectModify and EndDirectModify.

If the BeginDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

TupleTableSlot *
IterateDirectModify (ForeignScanState *node);

When the INSERT, UPDATE or DELETE query doesn’t have a RETURNING clause, just return NULL after a direct modification on the remote server. When the query has the clause, fetch one result containing the data needed for the RETURNING calculation, returning it in a tuple table slot (the node’s ScanTupleSlot should be used for this purpose). The data that was actually inserted, updated or deleted must be stored in the es_result_relation_info->ri_projectReturning->pi_exprContext->ecxt_scantuple of the node’s EState. Return NULL if no more rows are available. Note that this is called in a short-lived memory context that will be reset between invocations. Create a memory context in BeginDirectModify if you need longer-lived storage, or use the es_query_cxt of the node’s EState.

The rows returned must match the fdw_scan_tlist target list if one was supplied, otherwise they must match the row type of the foreign table being updated. If you choose to optimize away fetching columns that are not needed for the RETURNING calculation, you should insert nulls in those column positions, or else generate a fdw_scan_tlist list with those columns omitted.

Whether the query has the clause or not, the query’s reported row count must be incremented by the FDW itself. When the query doesn’t have the clause, the FDW must also increment the row count for the ForeignScanState node in the EXPLAIN ANALYZE case.

If the IterateDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

void
EndDirectModify (ForeignScanState *node);

Clean up following a direct modification on the remote server. It is normally not important to release palloc’d memory, but for example open files and connections to the remote server should be cleaned up.

If the EndDirectModify pointer is set to NULL, no attempts to execute a direct modification on the remote server are taken.

55.2.5. FDW Routines For Row Locking

If an FDW wishes to support late row locking (as described in Section 55.5), it must provide the following callback functions:
Chapter 55. Writing A Foreign Data Wrapper

RowMarkType
GetForeignRowMarkType (RangeTblEntry *rte,
                    LockClauseStrength strength);

Report which row-marking option to use for a foreign table. rte is the RangeTblEntry node for
the table and strength describes the lock strength requested by the relevant FOR UPDATE/SHARE
clause, if any. The result must be a member of the RowMarkType enum type.

This function is called during query planning for each foreign table that appears in an UPDATE,
DELETE, or SELECT FOR UPDATE/SHARE query and is not the target of UPDATE or DELETE.

If the GetForeignRowMarkType pointer is set to NULL, the ROW_MARK_COPY option is always used.
(This implies that RefetchForeignRow will never be called, so it need not be provided either.)

See Section 55.5 for more information.

HeapTuple
RefetchForeignRow (EState *estate,
                    ExecRowMark *erm,
                    Datum rowid,
                    bool *updated);

Re-fetch one tuple from the foreign table, after locking it if required. estate is global execution state
for the query. erms is the ExecRowMark struct describing the target foreign table and the row lock type
(if any) to acquire. rowid identifies the tuple to be fetched. updated is an output parameter.

This function should return a malloc’ed copy of the fetched tuple, or NULL if the row lock couldn’t be
obtained. The row lock type to acquire is defined by erm-\textgreater markType, which is the value previously
returned by GetForeignRowMarkType. (ROW_MARK_REFERENCE means to just re-fetch the tuple
without acquiring any lock, and ROW_MARK_COPY will never be seen by this routine.)

In addition, *updated should be set to true if what was fetched was an updated version of the
tuple rather than the same version previously obtained. (If the FDW cannot be sure about this, always
returning true is recommended.)

Note that by default, failure to acquire a row lock should result in raising an error; a NULL return is
only appropriate if the SKIP LOCKED option is specified by erm-\textgreater waitPolicy.

The rowid is the ctid value previously read for the row to be re-fetched. Although the rowid value
is passed as a Datum, it can currently only be a tid. The function API is chosen in hopes that it may
be possible to allow other data types for row IDs in future.

If the RefetchForeignRow pointer is set to NULL, attempts to re-fetch rows will fail with an error
message.

See Section 55.5 for more information.

bool
RecheckForeignScan (ForeignScanState *node, TupleTableSlot *slot);

Recheck that a previously-returned tuple still matches the relevant scan and join qualifiers, and possibly
provide a modified version of the tuple. For foreign data wrappers which do not perform join push-
down, it will typically be more convenient to set this to NULL and instead set fdw_recheck_quals
appropriately. When outer joins are pushed down, however, it isn’t sufficient to reapply the checks
relevant to all the base tables to the result tuple, even if all needed attributes are present, because
failure to match some qualifier might result in some attributes going to NULL, rather than in no tuple
being returned. RecheckForeignScan can recheck qualifiers and return true if they are still satisfied
and false otherwise, but it can also store a replacement tuple into the supplied slot.
Chapter 55. Writing A Foreign Data Wrapper

To implement join pushdown, a foreign data wrapper will typically construct an alternative local join plan which is used only for rechecks; this will become the outer subplan of the ForeignScan. When a recheck is required, this subplan can be executed and the resulting tuple can be stored in the slot. This plan need not be efficient since no base table will return more than one row; for example, it may implement all joins as nested loops. The function GetExistingLocalJoinPath may be used to search existing paths for a suitable local join path, which can be used as the alternative local join plan. GetExistingLocalJoinPath searches for an unparameterized path in the path list of the specified join relation. (If it does not find such a path, it returns NULL, in which case a foreign data wrapper may build the local path by itself or may choose not to create access paths for that join.)

55.2.6. FDW Routines for EXPLAIN

void ExplainForeignScan (ForeignScanState *node,
                          ExplainState *es);

Print additional EXPLAIN output for a foreign table scan. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainForeignScan pointer is set to NULL, no additional information is printed during EXPLAIN.

void ExplainForeignModify (ModifyTableState *mtstate,
                           ResultRelInfo *rinfo,
                           List *fdw_private,
                           int subplan_index,
                           struct ExplainState *es);

Print additional EXPLAIN output for a foreign table update. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ModifyTableState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case. The first four arguments are the same as for BeginForeignModify.

If the ExplainForeignModify pointer is set to NULL, no additional information is printed during EXPLAIN.

void ExplainDirectModify (ForeignScanState *node,
                          ExplainState *es);

Print additional EXPLAIN output for a direct modification on the remote server. This function can call ExplainPropertyText and related functions to add fields to the EXPLAIN output. The flag fields in es can be used to determine what to print, and the state of the ForeignScanState node can be inspected to provide run-time statistics in the EXPLAIN ANALYZE case.

If the ExplainDirectModify pointer is set to NULL, no additional information is printed during EXPLAIN.
55.2.7. FDW Routines for **ANALYZE**

```c
bool AnalyzeForeignTable (Relation relation,
    AcquireSampleRowsFunc *func,
    BlockNumber *totalpages);
```

This function is called when **ANALYZE** is executed on a foreign table. If the FDW can collect statistics for this foreign table, it should return `true`, and provide a pointer to a function that will collect sample rows from the table in `func`, plus the estimated size of the table in pages in `totalpages`. Otherwise, return `false`.

If the FDW does not support collecting statistics for any tables, the `AnalyzeForeignTable` pointer can be set to `NULL`.

If provided, the sample collection function must have the signature

```c
int AcquireSampleRowsFunc (Relation relation, int elevel,
    HeapTuple *rows, int targrows,
    double *totalrows,
    double *totaldeadrows);
```

A random sample of up to `targrows` rows should be collected from the table and stored into the caller-provided `rows` array. The actual number of rows collected must be returned. In addition, store estimates of the total numbers of live and dead rows in the table into the output parameters `totalrows` and `totaldeadrows`. (Set `totaldeadrows` to zero if the FDW does not have any concept of dead rows.)

55.2.8. FDW Routines For **IMPORT FOREIGN SCHEMA**

```c
List * ImportForeignSchema (ImportForeignSchemaStmt *stmt, Oid serverOid);
```

Obtain a list of foreign table creation commands. This function is called when executing **IMPORT FOREIGN SCHEMA**, and is passed the parse tree for that statement, as well as the OID of the foreign server to use. It should return a list of C strings, each of which must contain a **CREATE FOREIGN TABLE** command. These strings will be parsed and executed by the core server.

Within the `ImportForeignSchemaStmt` struct, `remote_schema` is the name of the remote schema from which tables are to be imported. `list_type` identifies how to filter table names: `FDW_IMPORTED_SCHEMA_ALL` means that all tables in the remote schema should be imported (in this case `table_list` is empty), `FDW_IMPORTED_SCHEMA_LIMIT_TO` means to include only tables listed in `table_list`, and `FDW_IMPORTED_SCHEMA_EXCEPT` means to exclude the tables listed in `table_list`. `options` is a list of options used for the import process. The meanings of the options are up to the FDW. For example, an FDW could use an option to define whether the **NOT NULL** attributes of columns should be imported. These options need not have anything to do with those supported by the FDW as database object options.

The FDW may ignore the `local_schema` field of the `ImportForeignSchemaStmt`, because the core server will automatically insert that name into the parsed **CREATE FOREIGN TABLE** commands.

The FDW does not have to concern itself with implementing the filtering specified by `list_type` and `table_list`, either, as the core server will automatically skip any returned commands for tables.
excluded according to those options. However, it’s often useful to avoid the work of creating commands for excluded tables in the first place. The function `IsImportableForeignTable()` may be useful to test whether a given foreign-table name will pass the filter.

If the FDW does not support importing table definitions, the `ImportForeignSchema` pointer can be set to `NULL`.

### 55.2.9. FDW Routines for Parallel Execution

A `ForeignScan` node can, optionally, support parallel execution. A parallel `ForeignScan` will be executed in multiple processes and should return each row only once across all cooperating processes. To do this, processes can coordinate through fixed size chunks of dynamic shared memory. This shared memory is not guaranteed to be mapped at the same address in every process, so pointers may not be used. The following callbacks are all optional in general, but required if parallel execution is to be supported.

```c
bool IsForeignScanParallelSafe(PlannerInfo *root, RelOptInfo *rel, RangeTblEntry *rte);
```

Test whether a scan can be performed within a parallel worker. This function will only be called when the planner believes that a parallel plan might be possible, and should return true if it is safe for that scan to run within a parallel worker. This will generally not be the case if the remote data source has transaction semantics, unless the worker’s connection to the data can somehow be made to share the same transaction context as the leader.

If this callback is not defined, it is assumed that the scan must take place within the parallel leader. Note that returning true does not mean that the scan itself can be done in parallel, only that the scan can be performed within a parallel worker. Therefore, it can be useful to define this method even when parallel execution is not supported.

```c
Size EstimateDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes.

```c
void InitializeDSMForeignScan(ForeignScanState *node, ParallelContext *pcxt, void *coordinate);
```

Initialize the dynamic shared memory that will be required for parallel operation; `coordinate` points to an amount of allocated space equal to the return value of `EstimateDSMForeignScan`.

```c
void InitializeWorkerForeignScan(ForeignScanState *node, shm_toc *toc, void *coordinate);
```

Initialize a parallel worker’s custom state based on the shared state set up in the leader by `InitializeDSMForeignScan`. This callback is optional, and needs only be supplied if this custom path supports parallel execution.
55.3. Foreign Data Wrapper Helper Functions

Several helper functions are exported from the core server so that authors of foreign data wrappers can get easy access to attributes of FDW-related objects, such as FDW options. To use any of these functions, you need to include the header file foreign/foreign.h in your source file. That header also defines the struct types that are returned by these functions.

ForeignDataWrapper *
    GetForeignDataWrapper(Oid fdwid);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given OID. A ForeignDataWrapper object contains properties of the FDW (see foreign/foreign.h for details).

ForeignServer *
    GetForeignServer(Oid serverid);

This function returns a ForeignServer object for the foreign server with the given OID. A ForeignServer object contains properties of the server (see foreign/foreign.h for details).

UserMapping *
    GetUserMapping(Oid userid, Oid serverid);

This function returns a UserMapping object for the user mapping of the given role on the given server. (If there is no mapping for the specific user, it will return the mapping for PUBLIC, or throw error if there is none.) A UserMapping object contains properties of the user mapping (see foreign/foreign.h for details).

ForeignTable *
    GetForeignTable(Oid relid);

This function returns a ForeignTable object for the foreign table with the given OID. A ForeignTable object contains properties of the foreign table (see foreign/foreign.h for details).

List *
    GetForeignColumnOptions(Oid relid, AttrNumber attnum);

This function returns the per-column FDW options for the column with the given foreign table OID and attribute number, in the form of a list of DefElem. NIL is returned if the column has no options.

Some object types have name-based lookup functions in addition to the OID-based ones:

ForeignDataWrapper *
    GetForeignDataWrapperByName(const char *name, bool missing_ok);

This function returns a ForeignDataWrapper object for the foreign-data wrapper with the given name. If the wrapper is not found, return NULL if missing_ok is true, otherwise raise an error.

ForeignServer *
    GetForeignServerByName(const char *name, bool missing_ok);

This function returns a ForeignServer object for the foreign server with the given name. If the server is not found, return NULL if missing_ok is true, otherwise raise an error.
55.4. Foreign Data Wrapper Query Planning

The FDW callback functions GetForeignRelSize, GetForeignPaths, GetForeignPlan, PlanForeignModify, GetForeignJoinPaths, GetForeignUpperPaths, and PlanDirectModify must fit into the workings of the PostgreSQL planner. Here are some notes about what they must do.

The information in root and baserel can be used to reduce the amount of information that has to be fetched from the foreign table (and therefore reduce the cost). baserel->baserestrictinfo is particularly interesting, as it contains restriction quals (WHERE clauses) that should be used to filter the rows to be fetched. (The FDW itself is not required to enforce these quals, as the core executor can check them instead.) baserel->reltarget->exprs can be used to determine which columns need to be fetched; but note that it only lists columns that have to be emitted by the ForeignScan plan node, not columns that are used in qual evaluation but not output by the query.

Various private fields are available for the FDW planning functions to keep information in. Generally, whatever you store in FDW private fields should be palloc’d, so that it will be reclaimed at the end of planning.

baserel->fdw_private is a void pointer that is available for FDW planning functions to store information relevant to the particular foreign table. The core planner does not touch it except to initialize it to NULL when the RelOptInfo node is created. It is useful for passing information forward from GetForeignRelSize to GetForeignPaths and/or GetForeignPaths to GetForeignPlan, thereby avoiding recalculation.

GetForeignPaths can identify the meaning of different access paths by storing private information in the fdw_private field of ForeignPath nodes. fdw_private is declared as a List pointer, but could actually contain anything since the core planner does not touch it. However, best practice is to use a representation that’s dumpable by nodeToString, for use with debugging support available in the backend.

GetForeignPlan can examine the fdw_private field of the selected ForeignPath node, and can generate fdw_exprs and fdw_private lists to be placed in the ForeignScan plan node, where they will be available at execution time. Both of these lists must be represented in a form that copyObject knows how to copy. The fdw_private list has no other restrictions and is not interpreted by the core backend in any way. The fdw_exprs list, if not NIL, is expected to contain expression trees that are intended to be executed at run time. These trees will undergo post-processing by the planner to make them fully executable.

In GetForeignPlan, generally the passed-in target list can be copied into the plan node as-is. The passed scan_clauses list contains the same clauses as baserel->baserestrictinfo, but may be re-ordered for better execution efficiency. In simple cases the FDW can just strip RestrictInfo nodes from the scan_clauses list (using extract_actual_clauses) and put all the clauses into the plan node’s qual list, which means that all the clauses will be checked by the executor at run time. More complex FDWs may be able to check some of the clauses internally, in which case those clauses can be removed from the plan node’s qual list so that the executor doesn’t waste time rechecking them.

As an example, the FDW might identify some restriction clauses of the form foreign_variable = sub_expression, which it determines can be executed on the remote server given the locally-evaluated value of the sub_expression. The actual identification of such a clause should happen during GetForeignPaths, since it would affect the cost estimate for the path. The path’s fdw_private field would probably include a pointer to the identified clause’s RestrictInfo node. Then GetForeignPlan would remove that clause from scan_clauses, but add the sub_expression to fdw_exprs to ensure that it gets massaged into executable form. It would probably also put control information into the plan node’s fdw_private field to tell the execution functions what to do at run time. The query transmitted to the remote server would involve
something like `WHERE foreign_variable = $1`, with the parameter value obtained at run time from evaluation of the `fdw_exprs` expression tree.

Any clauses removed from the plan node’s qual list must instead be added to `fdw_recheck_quads` or rechecked by `RecheckForeignScan` in order to ensure correct behavior at the `READ COMMITTED` isolation level. When a concurrent update occurs for some other table involved in the query, the executor may need to verify that all of the original quals are still satisfied for the tuple, possibly against a different set of parameter values. Using `fdw_recheck_quads` is typically easier than implementing checks inside `RecheckForeignScan`, but this method will be insufficient when outer joins have been pushed down, since the join tuples in that case might have some fields go to NULL without rejecting the tuple entirely.

Another `ForeignScan` field that can be filled by FDWs is `fdw_scan_tlist`, which describes the tuples returned by the FDW for this plan node. For simple foreign table scans this can be set to `NIL`, implying that the returned tuples have the row type declared for the foreign table. A non-`NIL` value must be a target list (list of `TargetEntry`s) containing Vars and/or expressions representing the returned columns. This might be used, for example, to show that the FDW has omitted some columns that it noticed won’t be needed for the query. Also, if the FDW can compute expressions used by the query more cheaply than can be done locally, it could add those expressions to `fdw_scan_tlist`. Note that join plans (created from paths made by `GetForeignJoinPaths`) must always supply `fdw_scan_tlist` to describe the set of columns they will return.

The FDW should always construct at least one path that depends only on the table’s restriction clauses. In join queries, it might also choose to construct path(s) that depend on join clauses, for example `foreign_variable = local_variable`. Such clauses will not be found in `baserel->baserestrictinfo` but must be sought in the relation’s join lists. A path using such a clause is called a “parameterized path”. It must identify the other relations used in the selected join clause(s) with a suitable value of `param_info`; use `get_baserel_parampathinfo` to compute that value. In `GetForeignPlan`, the `local_variable` portion of the join clause would be added to `fdw_exprs`, and then at run time the case works the same as for an ordinary restriction clause.

If an FDW supports remote joins, `GetForeignJoinPaths` should produce `ForeignPath`s for potential remote joins in much the same way as `GetForeignPaths` works for base tables. Information about the intended join can be passed forward to `GetForeignPlan` in the same ways described above. However, `baserestrictinfo` is not relevant for join relations; instead, the relevant join clauses for a particular join are passed to `GetForeignJoinPaths` as a separate parameter (extra->restrictlist).

An FDW might additionally support direct execution of some plan actions that are above the level of scans and joins, such as grouping or aggregation. To offer such options, the FDW should generate paths and insert them into the appropriate `upper relation`. For example, a path representing remote aggregation should be inserted into the UPPERREL_GROUP_AGG relation, using `add_path`. This path will be compared on a cost basis with local aggregation performed by reading a simple scan path for the foreign relation (note that such a path must also be supplied, else there will be an error at plan time). If the remote-aggregation path wins, which it usually would, it will be converted into a plan in the usual way, by calling `GetForeignPlan`. The recommended place to generate such paths is in the `GetForeignUpperPaths` callback function, which is called for each upper relation (i.e., each post-scan/join processing step), if all the base relations of the query come from the same FDW.

`PlanForeignModify` and the other callbacks described in Section 55.2.4 are designed around the assumption that the foreign relation will be scanned in the usual way and then individual row updates will be driven by a local `ModifyTable` plan node. This approach is necessary for the general case where an update requires reading local tables as well as foreign tables. However, if the operation could be executed entirely by the foreign server, the FDW could generate a path representing that and insert it into the UPPERREL_FINAL upper relation, where it would compete against the `ModifyTable`...
approach. This approach could also be used to implement remote \texttt{SELECT FOR UPDATE}, rather than using the row locking callbacks described in Section 55.2.5. Keep in mind that a path inserted into \texttt{UPPERREL_FINAL} is responsible for implementing all behavior of the query.

When planning an \texttt{UPDATE} or \texttt{DELETE}, \texttt{PlanForeignModify} and \texttt{PlanDirectModify} can look up the \texttt{RelOptInfo} struct for the foreign table and make use of the \texttt{baserel->fdw_private} data previously created by the scan-planning functions. However, in \texttt{INSERT} the target table is not scanned so there is no \texttt{RelOptInfo} for it. The \texttt{List} returned by \texttt{PlanForeignModify} has the same restrictions as the \texttt{fdw_private} list of a \texttt{ForeignScan} plan node, that is it must contain only structures that \texttt{copyObject} knows how to copy.

\texttt{INSERT} with an \texttt{ON CONFLICT} clause does not support specifying the conflict target, as unique constraints or exclusion constraints on remote tables are not locally known. This in turn implies that \texttt{ON CONFLICT DO UPDATE} is not supported, since the specification is mandatory there.

55.5. Row Locking in Foreign Data Wrappers

If an FDW’s underlying storage mechanism has a concept of locking individual rows to prevent concurrent updates of those rows, it is usually worthwhile for the FDW to perform row-level locking with as close an approximation as practical to the semantics used in ordinary PostgreSQL tables. There are multiple considerations involved in this.

One key decision to be made is whether to perform early locking or late locking. In early locking, a row is locked when it is first retrieved from the underlying store, while in late locking, the row is locked only when it is known that it needs to be locked. (The difference arises because some rows may be discarded by locally-checked restriction or join conditions.) Early locking is much simpler and avoids extra round trips to a remote store, but it can cause locking of rows that need not have been locked, resulting in reduced concurrency or even unexpected deadlocks. Also, late locking is only possible if the row to be locked can be uniquely re-identified later. Preferably the row identifier should identify a specific version of the row, as PostgreSQL TIDs do.

By default, PostgreSQL ignores locking considerations when interfacing to FDWs, but an FDW can perform early locking without any explicit support from the core code. The API functions described in Section 55.2.5, which were added in PostgreSQL 9.5, allow an FDW to use late locking if it wishes.

An additional consideration is that in \texttt{READ COMMITTED} isolation mode, PostgreSQL may need to re-check restriction and join conditions against an updated version of some target tuple. Rechecking join conditions requires re-obtaining copies of the non-target rows that were previously joined to the target tuple. When working with standard PostgreSQL tables, this is done by including the TIDs of the non-target tables in the column list projected through the join, and then re-fetching non-target rows when required. This approach keeps the join data set compact, but it requires inexpensive re-fetch capability, as well as a TID that can uniquely identify the row version to be re-fetched. By default, therefore, the approach used with foreign tables is to include a copy of the entire row fetched from a foreign table in the column list projected through the join. This puts no special demands on the FDW but can result in reduced performance of merge and hash joins. An FDW that is capable of meeting the re-fetch requirements can choose to do it the first way.

For an \texttt{UPDATE} or \texttt{DELETE} on a foreign table, it is recommended that the \texttt{ForeignScan} operation on the target table perform early locking on the rows that it fetches, perhaps via the equivalent of \texttt{SELECT FOR UPDATE}. An FDW can detect whether a table is an \texttt{UPDATE/DELETE} target at plan time by comparing its \texttt{relid} to \texttt{root->parse->resultRelation}, or at execution time by using \texttt{ExecRelationIsTargetRelation()}. An alternative possibility is to perform late locking within the \texttt{ExecForeignUpdate} or \texttt{ExecForeignDelete} callback, but no special support is provided for this.
For foreign tables that are specified to be locked by a `SELECT FOR UPDATE/SHARE` command, the `ForeignScan` operation can again perform early locking by fetching tuples with the equivalent of `SELECT FOR UPDATE/SHARE`. To perform late locking instead, provide the callback functions defined in Section 55.2.5. In `GetForeignRowMarkType`, select rowmark option `ROW_MARK_EXCLUSIVE`, `ROW_MARK_NOKEYEXCLUSIVE`, `ROW_MARK_SHARE`, or `ROW_MARK_KEYSHARE` depending on the requested lock strength. (The core code will act the same regardless of which of these four options you choose.) Elsewhere, you can detect whether a foreign table was specified to be locked by this type of command by using `get_plan_rowmark` at plan time, or `ExecFindRowMark` at execution time; you must check not only whether a non-null rowmark struct is returned, but that its `strength` field is not `LCS_NONE`.

Lastly, for foreign tables that are used in an `UPDATE`, `DELETE` or `SELECT FOR UPDATE/SHARE` command but are not specified to be row-locked, you can override the default choice to copy entire rows by having `GetForeignRowMarkType` select option `ROW_MARK_REFERENCE` when it sees lock strength `LCS_NONE`. This will cause `RefetchForeignRow` to be called with that value for `markType`; it should then re-fetch the row without acquiring any new lock. (If you have a `GetForeignRowMarkType` function but don’t wish to re-fetch unlocked rows, select option `ROW_MARK_COPY` for `LCS_NONE`.)

See `src/include/nodes/lockoptions.h`, the comments for `RowMarkType` and `PlanRowMark` in `src/include/nodes/plannodes.h`, and the comments for `ExecRowMark` in `src/include/nodes/execnodes.h` for additional information.
Chapter 56. Writing A Table Sampling Method

PostgreSQL’s implementation of the TABLESAMPLE clause supports custom table sampling methods, in addition to the BERNOULLI and SYSTEM methods that are required by the SQL standard. The sampling method determines which rows of the table will be selected when the TABLESAMPLE clause is used.

At the SQL level, a table sampling method is represented by a single SQL function, typically implemented in C, having the signature

```sql
method_name(internal) RETURNS tsm_handler
```

The name of the function is the same method name appearing in the TABLESAMPLE clause. The `internal` argument is a dummy (always having value zero) that simply serves to prevent this function from being called directly from a SQL command. The result of the function must be a `palloc`d struct of type `TsmRoutine`, which contains pointers to support functions for the sampling method. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 56.1.

In addition to function pointers, the `TsmRoutine` struct must provide these additional fields:

```c
List *parameterTypes
```

This is an OID list containing the data type OIDs of the parameter(s) that will be accepted by the TABLESAMPLE clause when this sampling method is used. For example, for the built-in methods, this list contains a single item with value `FLOAT4OID`, which represents the sampling percentage. Custom sampling methods can have more or different parameters.

```c
bool repeatable_across_queries
```

If `true`, the sampling method can deliver identical samples across successive queries, if the same parameters and `REPEATABLE` seed value are supplied each time and the table contents have not changed. When this is `false`, the `REPEATABLE` clause is not accepted for use with the sampling method.

```c
bool repeatable_across_scans
```

If `true`, the sampling method can deliver identical samples across successive scans in the same query (assuming unchanging parameters, seed value, and snapshot). When this is `false`, the planner will not select plans that would require scanning the sampled table more than once, since that might result in inconsistent query output.

The `TsmRoutine` struct type is declared in `src/include/access/tsmapi.h`, which see for additional details.

The table sampling methods included in the standard distribution are good references when trying to write your own. Look into the `src/backend/access/tablesample` subdirectory of the source tree for the built-in sampling methods, and into the `contrib` subdirectory for add-on methods.

### 56.1. Sampling Method Support Functions

The TSM handler function returns a `palloc`d `TsmRoutine` struct containing pointers to the support functions described below. Most of the functions are required, but some are optional, and those point-
void SampleScanGetSampleSize (PlannerInfo *root, RelOptInfo *baserel, List *paramexprs, BlockNumber *pages, double *tuples);

This function is called during planning. It must estimate the number of relation pages that will be read during a sample scan, and the number of tuples that will be selected by the scan. (For example, these might be determined by estimating the sampling fraction, and then multiplying the baserel->pages and baserel->tuples numbers by that, being sure to round the results to integral values.) The paramexprs list holds the expression(s) that are parameters to the TABLESAMPLE clause. It is recommended to use estimate_expression_value() to try to reduce these expressions to constants, if their values are needed for estimation purposes; but the function must provide size estimates even if they cannot be reduced, and it should not fail even if the values appear invalid (remember that they’re only estimates of what the run-time values will be). The pages and tuples parameters are outputs.

void InitSampleScan (SampleScanState *node, int eflags);

Initialize for execution of a SampleScan plan node. This is called during executor startup. It should perform any initialization needed before processing can start. The SampleScanState node has already been created, but its tsms_state field is NULL. The InitSampleScan function can alloc whatever internal state data is needed by the sampling method, and store a pointer to it in node->tsms_state. Information about the table to scan is accessible through other fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is not set up yet). eflags contains flag bits describing the executor’s operating mode for this plan node.

When (eflags & EXEC_FLAG_EXPLAIN_ONLY) is true, the scan will not actually be performed, so this function should only do the minimum required to make the node state valid for EXPLAIN and EndSampleScan.

This function can be omitted (set the pointer to NULL), in which case BeginSampleScan must perform all initialization needed by the sampling method.

void BeginSampleScan (SampleScanState *node, Datum *params, int nparams, uint32 seed);

Begin execution of a sampling scan. This is called just before the first attempt to fetch a tuple, and may be called again if the scan needs to be restarted. Information about the table to scan is accessible through fields of the SampleScanState node (but note that the node->ss.ss_currentScanDesc scan descriptor is not set up yet). The params array, of length nparams, contains the values of the parameters supplied in the TABLESAMPLE clause. These will have the number and types specified in the sampling method’s parameterTypes list, and have been checked to not be null. seed contains a seed to use for any random numbers generated within the sampling method; it is either a hash derived from the REPEATABLE value if one was given, or the result of random() if not.
This function may adjust the fields `node->use_bulkread` and `node->use_pagemode`. If `node->use_bulkread` is true, which it is by default, the scan will use a buffer access strategy that encourages recycling buffers after use. It might be reasonable to set this to false if the scan will visit only a small fraction of the table’s pages. If `node->use_pagemode` is true, which it is by default, the scan will perform visibility checking in a single pass for all tuples on each visited page. It might be reasonable to set this to false if the scan will select only a small fraction of the tuples on each visited page. That will result in fewer tuple visibility checks being performed, though each one will be more expensive because it will require more locking.

If the sampling method is marked `repeatable_across_scans`, it must be able to select the same set of tuples during a rescan as it did originally, that is a fresh call of `BeginSampleScan` must lead to selecting the same tuples as before (if the `TABLESAMPLE` parameters and seed don’t change).

```c
BlockNumber
NextSampleBlock (SampleScanState *node);
```

Returns the block number of the next page to be scanned, or `InvalidBlockNumber` if no pages remain to be scanned.

This function can be omitted (set the pointer to NULL), in which case the core code will perform a sequential scan of the entire relation. Such a scan can use synchronized scanning, so that the sampling method cannot assume that the relation pages are visited in the same order on each scan.

```c
OffsetNumber
NextSampleTuple (SampleScanState *node, 
                BlockNumber blockno, 
                OffsetNumber maxoffset);
```

Returns the offset number of the next tuple to be sampled on the specified page, or `InvalidOffsetNumber` if no tuples remain to be sampled. `maxoffset` is the largest offset number in use on the page.

**Note:** `NextSampleTuple` is not explicitly told which of the offset numbers in the range 1..`maxoffset` actually contain valid tuples. This is not normally a problem since the core code ignores requests to sample missing or invisible tuples; that should not result in any bias in the sample. However, if necessary, the function can examine `node->ss.ss_currentScanDesc->rs_vistuples[]` to identify which tuples are valid and visible. (This requires `node->use_pagemode` to be true.)

**Note:** `NextSampleTuple` must not assume that `blockno` is the same page number returned by the most recent `NextSampleBlock` call. It was returned by some previous `NextSampleBlock` call, but the core code is allowed to call `NextSampleBlock` in advance of actually scanning pages, so as to support prefetching. It is OK to assume that once sampling of a given page begins, successive `NextSampleTuple` calls all refer to the same page until `InvalidOffsetNumber` is returned.

```c
void
EndSampleScan (SampleScanState *node);
```

End the scan and release resources. It is normally not important to release `palloc’d` memory, but any externally-visible resources should be cleaned up. This function can be omitted (set the pointer to NULL) in the common case where no such resources exist.
Chapter 57. Writing A Custom Scan Provider

PostgreSQL supports a set of experimental facilities which are intended to allow extension modules to add new scan types to the system. Unlike a foreign data wrapper, which is only responsible for knowing how to scan its own foreign tables, a custom scan provider can provide an alternative method of scanning any relation in the system. Typically, the motivation for writing a custom scan provider will be to allow the use of some optimization not supported by the core system, such as caching or some form of hardware acceleration. This chapter outlines how to write a new custom scan provider.

Implementing a new type of custom scan is a three-step process. First, during planning, it is necessary to generate access paths representing a scan using the proposed strategy. Second, if one of those access paths is selected by the planner as the optimal strategy for scanning a particular relation, the access path must be converted to a plan. Finally, it must be possible to execute the plan and generate the same results that would have been generated for any other access path targeting the same relation.

57.1. Creating Custom Scan Paths

A custom scan provider will typically add paths for a base relation by setting the following hook, which is called after the core code has generated all the access paths it can for the relation (except for Gather paths, which are made after this call so that they can use partial paths added by the hook):

typedef void (*set_rel_pathlist_hook_type) (PlannerInfo *root,
    RelOptInfo *rel,
    Index rti,
    RangeTblEntry *rte);
extern PGDLLIMPORT set_rel_pathlist_hook_type set_rel_pathlist_hook;

Although this hook function can be used to examine, modify, or remove paths generated by the core system, a custom scan provider will typically confine itself to generating CustomPath objects and adding them to rel using add_path. The custom scan provider is responsible for initializing the CustomPath object, which is declared like this:

typedef struct CustomPath
{
    Path path;
    uint32 flags;
    List *custom_paths;
    List *custom_private;
    const CustomPathMethods *methods;
} CustomPath;

path must be initialized as for any other path, including the row-count estimate, start and total cost, and sort ordering provided by this path. flags is a bit mask, which should include CUSTOMPATH_SUPPORT_BACKWARD_SCAN if the custom path can support a backward scan and CUSTOMPATH_SUPPORT_MARK_RESTORE if it can support mark and restore. Both capabilities are optional. An optional custom_paths is a list of Path nodes used by this custom-path node; these will be transformed into Plan nodes by planner. custom_private can be used to store the custom
path’s private data. Private data should be stored in a form that can be handled by `nodeToString`, so that debugging routines that attempt to print the custom path will work as designed. `methods` must point to a (usually statically allocated) object implementing the required custom path methods, of which there is currently only one. The `LibraryName` and `SymbolName` fields must also be initialized so that the dynamic loader can resolve them to locate the method table.

A custom scan provider can also provide join paths. Just as for base relations, such a path must produce the same output as would normally be produced by the join it replaces. To do this, the join provider should set the following hook, and then within the hook function, create `CustomPath path(s)` for the join relation.

```c
typedef void (*set_join_pathlist_hook_type) (PlannerInfo *root,
                                          RelOptInfo *joinrel,
                                          RelOptInfo *outerrel,
                                          RelOptInfo *innerrel,
                                          JoinType jointype,
                                          JoinPathExtraData *extra);
extern PGDLLIMPORT set_join_pathlist_hook_type set_join_pathlist_hook;
```

This hook will be invoked repeatedly for the same join relation, with different combinations of inner and outer relations; it is the responsibility of the hook to minimize duplicated work.

### 57.1.1. Custom Scan Path Callbacks

```c
Plan *(*PlanCustomPath) (PlannerInfo *root,
                         RelOptInfo *rel,
                         CustomPath *best_path,
                         List *tlist,
                         List *clauses,
                         List *custom_plans);
```

Convert a custom path to a finished plan. The return value will generally be a `CustomScan` object, which the callback must allocate and initialize. See Section 57.2 for more details.

### 57.2. Creating Custom Scan Plans

A custom scan is represented in a finished plan tree using the following structure:

```c
typedef struct CustomScan
{
  Scan       scan;
  uint32     flags;
  List       *custom_plans;
  List       *custom_exprs;
  List       *custom_private;
  List       *custom_scan_tlist;
  Bitmapset  *custom_relids;
  const CustomScanMethods *methods;
} CustomScan;
```
Chapter 57. Writing A Custom Scan Provider

scan must be initialized as for any other scan, including estimated costs, target lists, qualifications, and so on. flags is a bit mask with the same meaning as in CustomPath. custom_plans can be used to store child Plan nodes. custom_exprs should be used to store expression trees that will need to be fixed up by setrefs.c and subselect.c, while custom_private should be used to store other private data that is only used by the custom scan provider itself. custom_scan_tlist can be NIL when scanning a base relation, indicating that the custom scan returns scan tuples that match the base relation’s row type. Otherwise it is a target list describing the actual scan tuples. custom_scan_tlist must be provided for joins, and could be provided for scans if the custom scan provider can compute some non-Var expressions. custom_relids is set by the core code to the set of relations (range table indexes) that this scan node handles; except when this scan is replacing a join, it will have only one member. methods must point to a (usually statically allocated) object implementing the required custom scan methods, which are further detailed below.

When a CustomScan scans a single relation, scan.scanrelid must be the range table index of the table to be scanned. When it replaces a join, scan.scanrelid should be zero.

Plan trees must be able to be duplicated using copyObject, so all the data stored within the “custom” fields must consist of nodes that that function can handle. Furthermore, custom scan providers cannot substitute a larger structure that embeds a CustomScan for the structure itself, as would be possible for a CustomPath or CustomScanState.

57.2.1. Custom Scan Plan Callbacks

Node *(*CreateCustomScanState) (CustomScan *cscan);

Allocate a CustomScanState for this CustomScan. The actual allocation will often be larger than required for an ordinary CustomScanState, because many providers will wish to embed that as the first field of a larger structure. The value returned must have the node tag and methods set appropriately, but other fields should be left as zeroes at this stage; after ExecInitCustomScan performs basic initialization, the BeginCustomScan callback will be invoked to give the custom scan provider a chance to do whatever else is needed.

57.3. Executing Custom Scans

When a CustomScan is executed, its execution state is represented by a CustomScanState, which is declared as follows:

typedef struct CustomScanState
{
    ScanState ss;
    uint32 flags;
    const CustomExecMethods *methods;
} CustomScanState;

ss is initialized as for any other scan state, except that if the scan is for a join rather than a base relation, ss.ss_currentRelation is left NULL. flags is a bit mask with the same meaning as in CustomPath and CustomScan. methods must point to a (usually statically allocated) object implementing the required custom scan state methods, which are further detailed below. Typically, a
CustomScanState, which need not support `copyObject`, will actually be a larger structure embedding the above as its first member.

### 57.3.1. Custom Scan Execution Callbacks

```c
void (*BeginCustomScan) (CustomScanState *node,
                          EState *estate,
                          int eflags);
```

Complete initialization of the supplied `CustomScanState`. Standard fields have been initialized by `ExecInitCustomScan`, but any private fields should be initialized here.

```c
TupleTableSlot *(*ExecCustomScan) (CustomScanState *node);
```

Fetch the next scan tuple. If any tuples remain, it should fill `ps_ResultTupleSlot` with the next tuple in the current scan direction, and then return the tuple slot. If not, `NULL` or an empty slot should be returned.

```c
void (*EndCustomScan) (CustomScanState *node);
```

Clean up any private data associated with the `CustomScanState`. This method is required, but it does not need to do anything if there is no associated data or it will be cleaned up automatically.

```c
void (*ReScanCustomScan) (CustomScanState *node);
```

Rewind the current scan to the beginning and prepare to rescan the relation.

```c
void (*MarkPosCustomScan) (CustomScanState *node);
```

Save the current scan position so that it can subsequently be restored by the `RestrPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```c
void (*RestrPosCustomScan) (CustomScanState *node);
```

Restore the previous scan position as saved by the `MarkPosCustomScan` callback. This callback is optional, and need only be supplied if the `CUSTOMPATH_SUPPORT_MARK_RESTORE` flag is set.

```c
Size (*EstimateDSMCustomScan) (CustomScanState *node,
                                 ParallelContext *pcxt);
```

Estimate the amount of dynamic shared memory that will be required for parallel operation. This may be higher than the amount that will actually be used, but it must not be lower. The return value is in bytes. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```c
void (*InitializeDSMCustomScan) (CustomScanState *node,
                                 ParallelContext *pcxt,
                                 void *coordinate);
```
Chapter 57. Writing A Custom Scan Provider

Initialize the dynamic shared memory that will be required for parallel operation; coordinate points to an amount of allocated space equal to the return value of `EstimateDSMCustomScan`. This callback is optional, and need only be supplied if this custom scan provider supports parallel execution.

```c
void (*InitializeWorkerCustomScan) (CustomScanState *node,
    shm_toc *toc,
    void *coordinate);
```

Initialize a parallel worker’s custom state based on the shared state set up in the leader by `InitializeDSMCustomScan`. This callback is optional, and needs only be supplied if this custom path supports parallel execution.

```c
void (*ExplainCustomScan) (CustomScanState *node,
    List *ancestors,
    ExplainState *es);
```

Output additional information for `EXPLAIN` of a custom-scan plan node. This callback is optional. Common data stored in the `ScanState`, such as the target list and scan relation, will be shown even without this callback, but the callback allows the display of additional, private state.
Chapter 58. Genetic Query Optimizer

Author: Written by Martin Utesch (<utesch@aut.tu-freiberg.de>) for the Institute of Automatic Control at the University of Mining and Technology in Freiberg, Germany.

58.1. Query Handling as a Complex Optimization Problem

Among all relational operators the most difficult one to process and optimize is the *join*. The number of possible query plans grows exponentially with the number of joins in the query. Further optimization effort is caused by the support of a variety of *join methods* (e.g., nested loop, hash join, merge join in PostgreSQL) to process individual joins and a diversity of *indexes* (e.g., B-tree, hash, GiST and GIN in PostgreSQL) as access paths for relations.

The normal PostgreSQL query optimizer performs a *near-exhaustive search* over the space of alternative strategies. This algorithm, first introduced in IBM’s System R database, produces a near-optimal join order, but can take an enormous amount of time and memory space when the number of joins in the query grows large. This makes the ordinary PostgreSQL query optimizer inappropriate for queries that join a large number of tables.

The Institute of Automatic Control at the University of Mining and Technology, in Freiberg, Germany, encountered some problems when it wanted to use PostgreSQL as the backend for a decision support knowledge based system for the maintenance of an electrical power grid. The DBMS needed to handle large join queries for the inference machine of the knowledge based system. The number of joins in these queries made using the normal query optimizer infeasible.

In the following we describe the implementation of a *genetic algorithm* to solve the join ordering problem in a manner that is efficient for queries involving large numbers of joins.

58.2. Genetic Algorithms

The genetic algorithm (GA) is a heuristic optimization method which operates through randomized search. The set of possible solutions for the optimization problem is considered as a *population* of *individuals*. The degree of adaptation of an individual to its environment is specified by its *fitness*.

The coordinates of an individual in the search space are represented by *chromosomes*, in essence a set of character strings. A *gene* is a subsection of a chromosome which encodes the value of a single parameter being optimized. Typical encodings for a gene could be *binary* or *integer*.

Through simulation of the evolutionary operations *recombination*, *mutation*, and *selection* new generations of search points are found that show a higher average fitness than their ancestors.
According to the comp.ai.genetic FAQ it cannot be stressed too strongly that a GA is not a pure random search for a solution to a problem. A GA uses stochastic processes, but the result is distinctly non-random (better than random).

Figure 58-1. Structured Diagram of a Genetic Algorithm

58.3. Genetic Query Optimization (GEQO) in PostgreSQL

The GEQO module approaches the query optimization problem as though it were the well-known traveling salesman problem (TSP). Possible query plans are encoded as integer strings. Each string represents the join order from one relation of the query to the next. For example, the join tree

```
  1  /
  2 /
  3
  4
```

is encoded by the integer string ‘4-1-3-2’, which means, first join relation ‘4’ and ‘1’, then ‘3’, and then ‘2’, where 1, 2, 3, 4 are relation IDs within the PostgreSQL optimizer.

Specific characteristics of the GEQO implementation in PostgreSQL are:

- **Usage of a steady state GA** (replacement of the least fit individuals in a population, not whole-generational replacement) allows fast convergence towards improved query plans. This is essential for query handling with reasonable time;
Chapter 58. Genetic Query Optimizer

- Usage of *edge recombination crossover* which is especially suited to keep edge losses low for the solution of the TSP by means of a GA;
- Mutation as genetic operator is deprecated so that no repair mechanisms are needed to generate legal TSP tours.

Parts of the GEQO module are adapted from D. Whitley’s Genitor algorithm.

The GEQO module allows the PostgreSQL query optimizer to support large join queries effectively through non-exhaustive search.

### 58.3.1. Generating Possible Plans with GEQO

The GEQO planning process uses the standard planner code to generate plans for scans of individual relations. Then join plans are developed using the genetic approach. As shown above, each candidate join plan is represented by a sequence in which to join the base relations. In the initial stage, the GEQO code simply generates some possible join sequences at random. For each join sequence considered, the standard planner code is invoked to estimate the cost of performing the query using that join sequence. (For each step of the join sequence, all three possible join strategies are considered; and all the initially-determined relation scan plans are available. The estimated cost is the cheapest of these possibilities.) Join sequences with lower estimated cost are considered “more fit” than those with higher cost. The genetic algorithm discards the least fit candidates. Then new candidates are generated by combining genes of more-fit candidates — that is, by using randomly-chosen portions of known low-cost join sequences to create new sequences for consideration. This process is repeated until a preset number of join sequences have been considered; then the best one found at any time during the search is used to generate the finished plan.

This process is inherently nondeterministic, because of the randomized choices made during both the initial population selection and subsequent “mutation” of the best candidates. To avoid surprising changes of the selected plan, each run of the GEQO algorithm restarts its random number generator with the current geqo_seed parameter setting. As long as geqo_seed and the other GEQO parameters are kept fixed, the same plan will be generated for a given query (and other planner inputs such as statistics). To experiment with different search paths, try changing geqo_seed.

### 58.3.2. Future Implementation Tasks for PostgreSQL GEQO

Work is still needed to improve the genetic algorithm parameter settings. In file src/backend/optimizer/geqo/geqo_main.c, routines gimme_pool_size and gimme_number_generations, we have to find a compromise for the parameter settings to satisfy two competing demands:

- Optimality of the query plan
- Computing time

In the current implementation, the fitness of each candidate join sequence is estimated by running the standard planner’s join selection and cost estimation code from scratch. To the extent that different candidates use similar sub-sequences of joins, a great deal of work will be repeated. This could be made significantly faster by retaining cost estimates for sub-joins. The problem is to avoid expending unreasonable amounts of memory on retaining that state.
At a more basic level, it is not clear that solving query optimization with a GA algorithm designed for TSP is appropriate. In the TSP case, the cost associated with any substring (partial tour) is independent of the rest of the tour, but this is certainly not true for query optimization. Thus it is questionable whether edge recombination crossover is the most effective mutation procedure.

Chapter 59. Index Access Method Interface Definition

This chapter defines the interface between the core PostgreSQL system and *index access methods*, which manage individual index types. The core system knows nothing about indexes beyond what is specified here, so it is possible to develop entirely new index types by writing add-on code.

All indexes in PostgreSQL are what are known technically as *secondary indexes*; that is, the index is physically separate from the table file that it describes. Each index is stored as its own physical *relation* and so is described by an entry in the `pg_class` catalog. The contents of an index are entirely under the control of its index access method. In practice, all index access methods divide indexes into standard-size pages so that they can use the regular storage manager and buffer manager to access the index contents. (All the existing index access methods furthermore use the standard page layout described in Section 65.6, and most use the same format for index tuple headers; but these decisions are not forced on an access method.)

An index is effectively a mapping from some data key values to *tuple identifiers*, or TIDs, of row versions (tuples) in the index’s parent table. A TID consists of a block number and an item number within that block (see Section 65.6). This is sufficient information to fetch a particular row version from the table. Indexes are not directly aware that under MVCC, there might be multiple extant versions of the same logical row; to an index, each tuple is an independent object that needs its own index entry. Thus, an update of a row always creates all-new index entries for the row, even if the key values did not change. (HOT tuples are an exception to this statement; but indexes do not deal with those, either.) Index entries for dead tuples are reclaimed (by vacuuming) when the dead tuples themselves are reclaimed.

59.1. Basic API Structure for Indexes

Each index access method is described by a row in the `pg_am` system catalog. The `pg_am` entry specifies a name and a *handler function* for the access method. These entries can be created and deleted using the CREATE ACCESS METHOD and DROP ACCESS METHOD SQL commands.

An index access method handler function must be declared to accept a single argument of type `internal` and to return the pseudo-type `index_am_handler`. The argument is a dummy value that simply serves to prevent handler functions from being called directly from SQL commands. The result of the function must be a `palloc`d struct of type `IndexAmRoutine`, which contains everything that the core code needs to know to make use of the index access method. The `IndexAmRoutine` struct, also called the access method’s *API struct*, includes fields specifying assorted fixed properties of the access method, such as whether it can support multicoloumn indexes. More importantly, it contains pointers to support functions for the access method, which do all of the real work to access indexes. These support functions are plain C functions and are not visible or callable at the SQL level. The support functions are described in Section 59.2.

The structure `IndexAmRoutine` is defined thus:

```c
typedef struct IndexAmRoutine
{
    NodeTag type;
} IndexAmRoutine;
```
Chapter 59. Index Access Method Interface Definition

/*

ammarkpos_function ammarkpos;  /* can be NULL */
amrestrpos_function amrestrpos;  /* can be NULL */
}

To be useful, an index access method must also have one or more operator families and operator classes defined in pg_opfamily, pg_opclass, pg_amop, and pg_amproc. These entries allow the planner to determine what kinds of query qualifications can be used with indexes of this access
method. Operator families and classes are described in Section 36.14, which is prerequisite material for reading this chapter.

An individual index is defined by a pg_class entry that describes it as a physical relation, plus a pg_index entry that shows the logical content of the index — that is, the set of index columns it has and the semantics of those columns, as captured by the associated operator classes. The index columns (key values) can be either simple columns of the underlying table or expressions over the table rows. The index access method normally has no interest in where the index key values come from (it is always handed precomputed key values) but it will be very interested in the operator class information in pg_index. Both of these catalog entries can be accessed as part of the Relation data structure that is passed to all operations on the index.

Some of the flag fields of IndexAmRoutine have nonobvious implications. The requirements of amcanunique are discussed in Section 59.5. The amcanmulticol flag asserts that the access method supports multicol indexes, while amoptionalkey asserts that it allows scans where no indexable restriction clause is given for the first index column. When amcanmulticol is false, amoptionalkey essentially says whether the access method supports full-index scans without any restriction clause. Access methods that support multiple index columns must support scans that omit restrictions on any or all of the columns after the first; however they are permitted to require some restriction to appear for the first index column, and this is signaled by setting amoptionalkey false. One reason that an index AM might set amoptionalkey false is if it doesn’t index null values. Since most indexable operators are strict and hence cannot return true for null inputs, it is at first sight attractive to not store index entries for null values: they could never be returned by an index scan anyway. However, this argument fails when an index scan has no restriction clause for a given index column. In practice this means that indexes that have amoptionalkey true must index nulls, since the planner might decide to use such an index with no scan keys at all. A related restriction is that an index access method that supports multiple index columns must support indexing null values in columns after the first, because the planner will assume the index can be used for queries that do not restrict these columns. For example, consider an index on (a,b) and a query with WHERE a = 4. The system will assume the index can be used to scan for rows with a = 4, which is wrong if the index omits rows where b is null. It is, however, OK to omit rows where the first indexed column is null. An index access method that does index nulls may also set amsearchnulls, indicating that it supports IS NULL and IS NOT NULL clauses as search conditions.

59.2. Index Access Method Functions

The index construction and maintenance functions that an index access method must provide in IndexAmRoutine are:

IndexBuildResult *

ambuild (Relation heapRelation,
           Relation indexRelation,
           IndexInfo *indexInfo);

Build a new index. The index relation has been physically created, but is empty. It must be filled in with whatever fixed data the access method requires, plus entries for all tuples already existing in the table. Ordinarily the ambuild function will call IndexBuildHeapScan() to scan the table for existing tuples and compute the keys that need to be inserted into the index. The function must return a palloc’d struct containing statistics about the new index.

void

ambuildempty (Relation indexRelation);
Build an empty index, and write it to the initialization fork (INIT_FORKNUM) of the given relation. This method is called only for unlogged indexes; the empty index written to the initialization fork will be copied over the main relation fork on each server restart.

```plaintext
bool aminsert (Relation indexRelation,
                Datum *values,
                bool *isnull,
                ItemPointer heap_tid,
                Relation heapRelation,
                IndexUniqueCheck checkUnique);
```

Insert a new tuple into an existing index. The values and isnull arrays give the key values to be indexed, and heap_tid is the TID to be indexed. If the access method supports unique indexes (its amcanunique flag is true) then checkUnique indicates the type of uniqueness check to perform. This varies depending on whether the unique constraint is deferrable; see Section 59.5 for details. Normally the access method only needs the heapRelation parameter when performing uniqueness checking (since then it will have to look into the heap to verify tuple liveness).

The function’s Boolean result value is significant only when checkUnique is UNIQUE_CHECK_PARTIAL. In this case a TRUE result means the new entry is known unique, whereas FALSE means it might be non-unique (and a deferred uniqueness check must be scheduled). For other cases a constant FALSE result is recommended.

Some indexes might not index all tuples. If the tuple is not to be indexed, aminsert should just return without doing anything.

```plaintext
IndexBulkDeleteResult *
ambulkdelete (IndexVacuumInfo *info,
               IndexBulkDeleteResult *stats,
               IndexBulkDeleteCallback callback,
               void *callback_state);
```

Delete tuple(s) from the index. This is a “bulk delete” operation that is intended to be implemented by scanning the whole index and checking each entry to see if it should be deleted. The passed-in callback function must be called, in the style callback(TID, callback_state) returns bool, to determine whether any particular index entry, as identified by its referenced TID, is to be deleted. Must return either NULL or a palloc’d struct containing statistics about the effects of the deletion operation. It is OK to return NULL if no information needs to be passed on to amvacuumcleanup.

Because of limited maintenance_work_mem, ambulkdelete might need to be called more than once when many tuples are to be deleted. The stats argument is the result of the previous call for this index (it is NULL for the first call within a VACUUM operation). This allows the AM to accumulate statistics across the whole operation. Typically, ambulkdelete will modify and return the same struct if the passed stats is not null.

```plaintext
IndexBulkDeleteResult *
amvacuumcleanup (IndexVacuumInfo *info,
                   IndexBulkDeleteResult *stats);
```

Clean up after a VACUUM operation (zero or more ambulkdelete calls). This does not have to do anything beyond returning index statistics, but it might perform bulk cleanup such as reclaiming empty index pages. stats is whatever the last ambulkdelete call returned, or NULL if ambulkdelete was not called because no tuples needed to be deleted. If the result is not NULL it must be a palloc’d
struct. The statistics it contains will be used to update \texttt{pg\_class}, and will be reported by \texttt{VACUUM} if \texttt{VERBOSE} is given. It is OK to return \texttt{NULL} if the index was not changed at all during the \texttt{VACUUM} operation, but otherwise correct stats should be returned.

As of PostgreSQL 8.4, \texttt{amvacuumcleanup} will also be called at completion of an \texttt{ANALYZE} operation. In this case \texttt{stats} is always \texttt{NULL} and any return value will be ignored. This case can be distinguished by checking \texttt{info->analyze\_only}. It is recommended that the access method do nothing except post-insert cleanup in such a call, and that only in an autovacuum worker process.

```c
bool amcanreturn (Relation indexRelation, int attno);
```

Check whether the index can support \textit{index-only scans} on the given column, by returning the indexed column values for an index entry in the form of an \texttt{IndexTuple}. The attribute number is 1-based, i.e. the first column’s \texttt{attno} is 1. Returns \texttt{TRUE} if supported, else \texttt{FALSE}. If the access method does not support index-only scans at all, the \texttt{amcanreturn} field in its \texttt{IndexAmRoutine} struct can be set to \texttt{NULL}.

```c
void amcostestimate (PlannerInfo *root, IndexPath *path, double loop_count, Cost *indexStartupCost, Cost *indexTotalCost, Selectivity *indexSelectivity, double *indexCorrelation);
```

Estimate the costs of an index scan. This function is described fully in Section 59.6, below.

```c
bytea * amoptions (ArrayType *reloptions, bool validate);
```

Parse and validate the \texttt{reloptions} array for an index. This is called only when a non-null \texttt{reloptions} array exists for the index. \texttt{reloptions} is a \texttt{text} array containing entries of the form \texttt{name=value}. The function should construct a \texttt{bytea} value, which will be copied into the \texttt{rd\_options} field of the index’s relcache entry. The data contents of the \texttt{bytea} value are open for the access method to define; most of the standard access methods use \texttt{struct StdRdOptions}. When \texttt{validate} is true, the function should report a suitable error message if any of the options are unrecognized or have invalid values; when \texttt{validate} is false, invalid entries should be silently ignored. (\texttt{validate} is false when loading options already stored in \texttt{pg\_catalog}; an invalid entry could only be found if the access method has changed its rules for options, and in that case ignoring obsolete entries is appropriate.) It is OK to return \texttt{NULL} if default behavior is wanted.

```c
bool amproperty (Oid index_oid, int attno, IndexAMProperty prop, const char *propname, bool *res, bool *isnull);
```

The \texttt{amproperty} method allows index access methods to override the default behavior of \texttt{pg\_index\_column\_has\_property} and related functions. If the access method does not have any special behavior for index property inquiries, the \texttt{amproperty} field in its \texttt{IndexAmRoutine} struct can be set to \texttt{NULL}. Otherwise, the \texttt{amproperty} method will be called with \texttt{index\_oid} and \texttt{attno} both zero for \texttt{pg\_indexam\_has\_property} calls, or with \texttt{index\_oid} valid and \texttt{attno} zero.
for `pg_index_has_property` calls, or with `index_oid` valid and `attno` greater than zero for `pg_index_column_has_property` calls. `prop` is an enum value identifying the property being tested, while `propname` is the original property name string. If the core code does not recognize the property name then `prop` is `AMPROP_UNKNOWN`. Access methods can define custom property names by checking `propname` for a match (use `pg_strcasecmp` to match, for consistency with the core code); for names known to the core code, it’s better to inspect `prop`. If the `amproperty` method returns `true` then it has determined the property test result: it must set `*res` to the boolean value to return, or set `*isnull` to `true` to return a NULL. (Both of the referenced variables are initialized to `false` before the call.) If the `amproperty` method returns `false` then the core code will proceed with its normal logic for determining the property test result.

Access methods that support ordering operators should implement `AMPROP_DISTANCE_ORDERABLE` property testing, as the core code does not know how to do that and will return NULL. It may also be advantageous to implement `AMPROP_RETURNABLE` testing, if that can be done more cheaply than by opening the index and calling `amcanreturn`, which is the core code’s default behavior. The default behavior should be satisfactory for all other standard properties.

```c
bool
amvalidate (Oid opclassoid);
```

Validate the catalog entries for the specified operator class, so far as the access method can reasonably do that. For example, this might include testing that all required support functions are provided. The `amvalidate` function must return `false` if the opclass is invalid. Problems should be reported with `ereport` messages.

The purpose of an index, of course, is to support scans for tuples matching an indexable `WHERE` condition, often called a `qualifier` or `scan key`. The semantics of index scanning are described more fully in Section 59.3, below. An index access method can support “plain” index scans, “bitmap” index scans, or both. The scan-related functions that an index access method must or may provide are:

```c
IndexScanDesc
ambeginscan (Relation indexRelation,
    int nkeys,
    int norderbys);
```

Prepare for an index scan. The `nkeys` and `norderbys` parameters indicate the number of quals and ordering operators that will be used in the scan; these may be useful for space allocation purposes. Note that the actual values of the scan keys aren’t provided yet. The result must be a `palloc’d` struct. For implementation reasons the index access method `must` create this struct by calling `RelationGetIndexScan()`. In most cases `ambeginscan` does little beyond making that call and perhaps acquiring locks; the interesting parts of index-scan startup are in `amrescan`.

```c
void
amrescan (IndexScanDesc scan,
    ScanKey keys,
    int nkeys,
    ScanKey orderbys,
    int norderbys);
```

Start or restart an index scan, possibly with new scan keys. (To restart using previously-passed keys, NULL is passed for `keys` and/or `orderbys`.) Note that it is not allowed for the number of keys or order-by operators to be larger than what was passed to `ambeginscan`. In practice the restart feature is used when a new outer tuple is selected by a nested-loop join and so a new key comparison value is needed, but the scan key structure remains the same.
boolean amgettuple (IndexScanDesc scan,
    ScanDirection direction);

Fetch the next tuple in the given scan, moving in the given direction (forward or backward in the index). Returns TRUE if a tuple was obtained, FALSE if no matching tuples remain. In the TRUE case the tuple TID is stored into the scan structure. Note that “success” means only that the index contains an entry that matches the scan keys, not that the tuple necessarily still exists in the heap or will pass the caller’s snapshot test. On success, amgettuple must also set scan->xs_recheck to TRUE or FALSE. FALSE means it is certain that the index entry matches the scan keys. TRUE means this is not certain, and the conditions represented by the scan keys must be rechecked against the heap tuple after fetching it. This provision supports “lossy” index operators. Note that rechecking will extend only to the scan conditions; a partial index predicate (if any) is never rechecked by amgettuple callers.

If the index supports index-only scans (i.e., amcanreturn returns TRUE for it), then on success the AM must also check scan->xs_want_itup, and if that is true it must return the original indexed data for the index entry, in the form of an IndexTuple pointer stored at scan->xs_itup, with tuple descriptor scan->xs_itupdesc. (Management of the data referenced by the pointer is the access method’s responsibility. The data must remain good at least until the next amgettuple, amrescan, or amendscan call for the scan.)

The amgettuple function need only be provided if the access method supports “plain” index scans. If it doesn’t, the amgettuple field in its IndexAmRoutine struct must be set to NULL.

int64 amgetbitmap (IndexScanDesc scan,
    TIDBitmap *tbm);

Fetch all tuples in the given scan and add them to the caller-supplied TIDBitmap (that is, OR the set of tuple IDs into whatever set is already in the bitmap). The number of tuples fetched is returned (this might be just an approximate count, for instance some AMs do not detect duplicates). While inserting tuple IDs into the bitmap, amgetbitmap can indicate that rechecking of the scan conditions is required for specific tuple IDs. This is analogous to the xs_recheck output parameter of amgettuple. Note: in the current implementation, support for this feature is conflated with support for lossy storage of the bitmap itself, and therefore callers recheck both the scan conditions and the partial index predicate (if any) for recheckable tuples. That might not always be true, however. amgetbitmap and amgettuple cannot be used in the same index scan; there are other restrictions too when using amgetbitmap, as explained in Section 59.3.

The amgetbitmap function need only be provided if the access method supports “bitmap” index scans. If it doesn’t, the amgetbitmap field in its IndexAmRoutine struct must be set to NULL.

void amendscan (IndexScanDesc scan);

End a scan and release resources. The scan struct itself should not be freed, but any locks or pins taken internally by the access method must be released, as well as any other memory allocated by ambeginscan and other scan-related functions.

void ammarkpos (IndexScanDesc scan);

Mark current scan position. The access method need only support one remembered scan position per scan.
The `ammarkpos` function need only be provided if the access method supports ordered scans. If it doesn’t, the `ammarkpos` field in its `IndexAmRoutine` struct may be set to NULL.

```c
void
amrestrpos (IndexScanDesc scan);
```

Restore the scan to the most recently marked position.

The `amrestrpos` function need only be provided if the access method supports ordered scans. If it doesn’t, the `amrestrpos` field in its `IndexAmRoutine` struct may be set to NULL.

## 59.3. Index Scanning

In an index scan, the index access method is responsible for regurgitating the TIDs of all the tuples it has been told about that match the scan keys. The access method is not involved in actually fetching those tuples from the index’s parent table, nor in determining whether they pass the scan’s time qualification test or other conditions.

A scan key is the internal representation of a `WHERE` clause of the form `index_key operator constant`, where the index key is one of the columns of the index and the operator is one of the members of the operator family associated with that index column. An index scan has zero or more scan keys, which are implicitly ANDed — the returned tuples are expected to satisfy all the indicated conditions.

The access method can report that the index is lossy, or requires rechecks, for a particular query. This implies that the index scan will return all the entries that pass the scan key, plus possibly additional entries that do not. The core system’s index-scan machinery will then apply the index conditions again to the heap tuple to verify whether or not it really should be selected. If the recheck option is not specified, the index scan must return exactly the set of matching entries.

Note that it is entirely up to the access method to ensure that it correctly finds all and only the entries passing all the given scan keys. Also, the core system will simply hand off all the `WHERE` clauses that match the index keys and operator families, without any semantic analysis to determine whether they are redundant or contradictory. As an example, given `WHERE x > 4 AND x > 14` where `x` is a b-tree indexed column, it is left to the b-tree `amrescan` function to realize that the first scan key is redundant and can be discarded. The extent of preprocessing needed during `amrescan` will depend on the extent to which the index access method needs to reduce the scan keys to a “normalized” form.

Some access methods return index entries in a well-defined order, others do not. There are actually two different ways that an access method can support sorted output:

- Access methods that always return entries in the natural ordering of their data (such as btree) should set `amcanorder` to true. Currently, such access methods must use btree-compatible strategy numbers for their equality and ordering operators.

- Access methods that support ordering operators should set `amcanorderbyop` to true. This indicates that the index is capable of returning entries in an order satisfying `ORDER BY index_key operator constant`. Scan modifiers of that form can be passed to `amrescan` as described previously.

The `amgettuple` function has a direction argument, which can be either `ForwardScanDirection` (the normal case) or `BackwardScanDirection`. If the first call after `amrescan` specifies `BackwardScanDirection`, then the set of matching index entries is to be
scanned back-to-front rather than in the normal front-to-back direction, so amgettuple must return
the last matching tuple in the index, rather than the first one as it normally would. (This will only
occur for access methods that set amcanorder to true.) After the first call, amgettuple must
be prepared to advance the scan in either direction from the most recently returned entry. (But if
amcanbackward is false, all subsequent calls will have the same direction as the first one.)

Access methods that support ordered scans must support “marking” a position in a scan and later
returning to the marked position. The same position might be restored multiple times. However, only
one position need be remembered per scan; a new ammarkpos call overrides the previously marked
position. An access method that does not support ordered scans need not provide ammarkpos and
amrestrpos functions in IndexAmRoutine; set those pointers to NULL instead.

Both the scan position and the mark position (if any) must be maintained consistently in the face
of concurrent insertions or deletions in the index. It is OK if a freshly-inserted entry is not returned
by a scan that would have found the entry if it had existed when the scan started, or for the scan to
return such an entry upon rescanning or backing up even though it had not been returned the first time
through. Similarly, a concurrent delete might or might not be reflected in the results of a scan. What is
important is that insertions or deletions not cause the scan to miss or multiply return entries that were
not themselves being inserted or deleted.

If the index stores the original indexed data values (and not some lossy representation of them), it is
useful to support index-only scans, in which the index returns the actual data not just the TID of the
heap tuple. This will only avoid I/O if the visibility map shows that the TID is on an all-visible page;
else the heap tuple must be visited anyway to check MVCC visibility. But that is no concern of the
access method’s.

Instead of using amgettuple, an index scan can be done with amgetbitmap to fetch all tuples in one
call. This can be noticeably more efficient than amgettuple because it allows avoiding lock/unlock
cycles within the access method. In principle amgetbitmap should have the same effects as repeated
amgettuple calls, but we impose several restrictions to simplify matters. First of all, amgetbitmap
returns all tuples at once and marking or restoring scan positions isn’t supported. Secondly, the tu-
uples are returned in a bitmap which doesn’t have any specific ordering, which is why amgetbitmap
doesn’t take a direction argument. (Ordering operators will never be supplied for such a scan,
either.) Also, there is no provision for index-only scans with amgetbitmap, since there is no way
to return the contents of index tuples. Finally, amgetbitmap does not guarantee any locking of the
returned tuples, with implications spelled out in Section 59.4.

Note that it is permitted for an access method to implement only amgetbitmap and not amgettuple,
or vice versa, if its internal implementation is unsuited to one API or the other.

59.4. Index Locking Considerations

Index access methods must handle concurrent updates of the index by multiple processes. The
core PostgreSQL system obtains AccessShareLock on the index during an index scan, and
RowExclusiveLock when updating the index (including plain VACUUM). Since these lock types do
not conflict, the access method is responsible for handling any fine-grained locking it might need. An
exclusive lock on the index as a whole will be taken only during index creation, destruction, or
REINDEX.

Building an index type that supports concurrent updates usually requires extensive and subtle analysis
of the required behavior. For the b-tree and hash index types, you can read about the design decisions
involved in src/backend/access/nbtree/README and src/backend/access/hash/README.
Aside from the index’s own internal consistency requirements, concurrent updates create issues about consistency between the parent table (the *heap*) and the index. Because PostgreSQL separates accesses and updates of the heap from those of the index, there are windows in which the index might be inconsistent with the heap. We handle this problem with the following rules:

- A new heap entry is made before making its index entries. (Therefore a concurrent index scan is likely to fail to see the heap entry. This is okay because the index reader would be uninterested in an uncommitted row anyway. But see Section 59.5.)
- When a heap entry is to be deleted (by *VACUUM*), all its index entries must be removed first.
- An index scan must maintain a pin on the index page holding the item last returned by *amgettuple*, and *ambulkdelete* cannot delete entries from pages that are pinned by other backends. The need for this rule is explained below.

Without the third rule, it is possible for an index reader to see an index entry just before it is removed by *VACUUM*, and then to arrive at the corresponding heap entry after that was removed by *VACUUM*. This creates no serious problems if that item number is still unused when the reader reaches it, since an empty item slot will be ignored by *heap_fetch()*). But what if a third backend has already reused the item slot for something else? When using an MVCC-compliant snapshot, there is no problem because the new occupant of the slot is certain to be too new to pass the snapshot test. However, with a non-MVCC-compliant snapshot (such as *SnapshotAny*), it would be possible to accept and return a row that does not in fact match the scan keys. We could defend against this scenario by requiring the scan keys to be rechecked against the heap row in all cases, but that is too expensive. Instead, we use a pin on an index page as a proxy to indicate that the reader might still be “in flight” from the index entry to the matching heap entry. Making *ambulkdelete* block on such a pin ensures that *VACUUM* cannot delete the heap entry before the reader is done with it. This solution costs little in run time, and adds blocking overhead only in the rare cases where there actually is a conflict.

This solution requires that index scans be “synchronous”: we have to fetch each heap tuple immediately after scanning the corresponding index entry. This is expensive for a number of reasons. A “asynchronous” scan in which we collect many TIDs from the index, and only visit the heap tuples sometime later, requires much less index locking overhead and can allow a more efficient heap access pattern. Per the above analysis, we must use the synchronous approach for non-MVCC-compliant snapshots, but an asynchronous scan is workable for a query using an MVCC snapshot.

In an *amgetbitmap* index scan, the access method does not keep an index pin on any of the returned tuples. Therefore it is only safe to use such scans with MVCC-compliant snapshots.

When the *ampredlocks* flag is not set, any scan using that index access method within a serializable transaction will acquire a nonblocking predicate lock on the full index. This will generate a read-write conflict with the insert of any tuple into that index by a concurrent serializable transaction. If certain patterns of read-write conflicts are detected among a set of concurrent serializable transactions, one of those transactions may be canceled to protect data integrity. When the flag is set, it indicates that the index access method implements finer-grained predicate locking, which will tend to reduce the frequency of such transaction cancellations.

### 59.5. Index Uniqueness Checks

PostgreSQL enforces SQL uniqueness constraints using *unique indexes*, which are indexes that disallow multiple entries with identical keys. An access method that supports this feature sets *amcanunique* true. (At present, only b-tree supports it.)
Chapter 59. Index Access Method Interface Definition

Because of MVCC, it is always necessary to allow duplicate entries to exist physically in an index: the entries might refer to successive versions of a single logical row. The behavior we actually want to enforce is that no MVCC snapshot could include two rows with equal index keys. This breaks down into the following cases that must be checked when inserting a new row into a unique index:

- If a conflicting valid row has been deleted by the current transaction, it’s okay. (In particular, since an UPDATE always deletes the old row version before inserting the new version, this will allow an UPDATE on a row without changing the key.)

- If a conflicting row has been inserted by an as-yet-uncommitted transaction, the would-be inserter must wait to see if that transaction commits. If it rolls back then there is no conflict. If it commits without deleting the conflicting row again, there is a uniqueness violation. (In practice we just wait for the other transaction to end and then redo the visibility check in toto.)

- Similarly, if a conflicting valid row has been deleted by an as-yet-uncommitted transaction, the would-be inserter must wait for that transaction to commit or abort, and then repeat the test.

Furthermore, immediately before reporting a uniqueness violation according to the above rules, the access method must recheck the liveness of the row being inserted. If it is committed dead then no violation should be reported. (This case cannot occur during the ordinary scenario of inserting a row that’s just been created by the current transaction. It can happen during CREATE UNIQUE INDEX CONCURRENTLY, however.)

We require the index access method to apply these tests itself, which means that it must reach into the heap to check the commit status of any row that is shown to have a duplicate key according to the index contents. This is without a doubt ugly and non-modular, but it saves redundant work: if we did a separate probe then the index lookup for a conflicting row would be essentially repeated while finding the place to insert the new row’s index entry. What’s more, there is no obvious way to avoid race conditions unless the conflict check is an integral part of insertion of the new index entry.

If the unique constraint is deferrable, there is additional complexity: we need to be able to insert an index entry for a new row, but defer any uniqueness-violation error until end of statement or even later. To avoid unnecessary repeat searches of the index, the index access method should do a preliminary uniqueness check during the initial insertion. If this shows that there is definitely no conflicting live tuple, we are done. Otherwise, we schedule a recheck to occur when it is time to enforce the constraint. If, at the time of the recheck, both the inserted tuple and some other tuple with the same key are live, then the error must be reported. (Note that for this purpose, “live” actually means “any tuple in the index entry’s HOT chain is live”.) To implement this, the aminsert function is passed a checkUnique parameter having one of the following values:

- UNIQUE_CHECK_NO indicates that no uniqueness checking should be done (this is not a unique index).

- UNIQUE_CHECK_YES indicates that this is a non-deferrable unique index, and the uniqueness check must be done immediately, as described above.

- UNIQUE_CHECK_PARTIAL indicates that the unique constraint is deferrable. PostgreSQL will use this mode to insert each row’s index entry. The access method must allow duplicate entries into the index, and report any potential duplicates by returning FALSE from aminsert. For each row for which FALSE is returned, a deferred recheck will be scheduled.

The access method must identify any rows which might violate the unique constraint, but it is not an error for it to report false positives. This allows the check to be done without waiting for other transactions to finish; conflicts reported here are not treated as errors and will be rechecked later, by which time they may no longer be conflicts.
Chapter 59. Index Access Method Interface Definition

- **UNIQUE_CHECK_EXISTING** indicates that this is a deferred recheck of a row that was reported as a potential uniqueness violation. Although this is implemented by calling `aminsert`, the access method must not insert a new index entry in this case. The index entry is already present. Rather, the access method must check to see if there is another live index entry. If so, and if the target row is also still live, report error.

It is recommended that in a **UNIQUE_CHECK_EXISTING** call, the access method further verify that the target row actually does have an existing entry in the index, and report error if not. This is a good idea because the index tuple values passed to `aminsert` will have been recomputed. If the index definition involves functions that are not really immutable, we might be checking the wrong area of the index. Checking that the target row is found in the recheck verifies that we are scanning for the same tuple values as were used in the original insertion.

### 59.6. Index Cost Estimation Functions

The `amcostestimate` function is given information describing a possible index scan, including lists of WHERE and ORDER BY clauses that have been determined to be usable with the index. It must return estimates of the cost of accessing the index and the selectivity of the WHERE clauses (that is, the fraction of parent-table rows that will be retrieved during the index scan). For simple cases, nearly all the work of the cost estimator can be done by calling standard routines in the optimizer; the point of having an `amcostestimate` function is to allow index access methods to provide index-type-specific knowledge, in case it is possible to improve on the standard estimates.

Each `amcostestimate` function must have the signature:

```c
void amcostestimate (PlannerInfo *root,
                     IndexPath *path,
                     double loop_count,
                     Cost *indexStartupCost,
                     Cost *indexTotalCost,
                     Selectivity *indexSelectivity,
                     double *indexCorrelation);
```

The first three parameters are inputs:

- `root`:
  The planner’s information about the query being processed.

- `path`:
  The index access path being considered. All fields except cost and selectivity values are valid.

- `loop_count`:
  The number of repetitions of the index scan that should be factored into the cost estimates. This will typically be greater than one when considering a parameterized scan for use in the inside of a nestloop join. Note that the cost estimates should still be for just one scan; a larger `loop_count` means that it may be appropriate to allow for some caching effects across multiple scans.

The last four parameters are pass-by-reference outputs:
Chapter 59. Index Access Method Interface Definition

*indexStartupCost

Set to cost of index start-up processing

*indexTotalCost

Set to total cost of index processing

*indexSelectivity

Set to index selectivity

*indexCorrelation

Set to correlation coefficient between index scan order and underlying table’s order

Note that cost estimate functions must be written in C, not in SQL or any available procedural language, because they must access internal data structures of the planner/optimizer.

The index access costs should be computed using the parameters used by src/backend/optimizer/path/costsize.c: a sequential disk block fetch has cost seq_page_cost, a nonsequential fetch has cost random_page_cost, and the cost of processing one index row should usually be taken as cpu_index_tuple_cost. In addition, an appropriate multiple of cpu_operator_cost should be charged for any comparison operators invoked during index processing (especially evaluation of the indexquals themselves).

The access costs should include all disk and CPU costs associated with scanning the index itself, but not the costs of retrieving or processing the parent-table rows that are identified by the index.

The “start-up cost” is the part of the total scan cost that must be expended before we can begin to fetch the first row. For most indexes this can be taken as zero, but an index type with a high start-up cost might want to set it nonzero.

The indexSelectivity should be set to the estimated fraction of the parent table rows that will be retrieved during the index scan. In the case of a lossy query, this will typically be higher than the fraction of rows that actually pass the given qual conditions.

The indexCorrelation should be set to the correlation (ranging between -1.0 and 1.0) between the index order and the table order. This is used to adjust the estimate for the cost of fetching rows from the parent table.

When loop_count is greater than one, the returned numbers should be averages expected for any one scan of the index.

Cost Estimation

A typical cost estimator will proceed as follows:

1. Estimate and return the fraction of parent-table rows that will be visited based on the given qual conditions. In the absence of any index-type-specific knowledge, use the standard optimizer function clauselist_selectivity():

   ```c
   *indexSelectivity = clauselist_selectivity(root, path->indexquals,
   path->indexinfo->rel->relid,
   JOIN_INNER, NULL);
   ```

2. Estimate the number of index rows that will be visited during the scan. For many index types this is the same as indexSelectivity times the number of rows in the index, but it might be more. (Note that the index’s size in pages and rows is available from the path->indexinfo struct.)

3. Estimate the number of index pages that will be retrieved during the scan. This might be just indexSelectivity times the index’s size in pages.
4. Compute the index access cost. A generic estimator might do this:

```c
/*
 * Our generic assumption is that the index pages will be read
 * sequentially, so they cost seq_page_cost each, not random_page_cost.
 * Also, we charge for evaluation of the indexquals at each index row.
 * All the costs are assumed to be paid incrementally during the scan.
 */

cost_qual_eval(&index_qual_cost, path->indexquals, root);
*indexStartupCost = index_qual_cost.startup;
*indexTotalCost = seq_page_cost * numIndexPages +
    (cpu_index_tuple_cost + index_qual_cost.per_tuple) * numIndexTuples;
```

However, the above does not account for amortization of index reads across repeated index scans.

5. Estimate the index correlation. For a simple ordered index on a single field, this can be retrieved from `pg_statistic`. If the correlation is not known, the conservative estimate is zero (no correlation).

Examples of cost estimator functions can be found in `src/backend/utils/adt/selfuncs.c`. 
Chapter 60. Generic WAL Records

Although all built-in WAL-logged modules have their own types of WAL records, there is also a generic WAL record type, which describes changes to pages in a generic way. This is useful for extensions that provide custom access methods, because they cannot register their own WAL redo routines.

The API for constructing generic WAL records is defined in `access/generic_xlog.h` and implemented in `access/transam/generic_xlog.c`.

To perform a WAL-logged data update using the generic WAL record facility, follow these steps:

1. `state = GenericXLogStart(relation)` — start construction of a generic WAL record for the given relation.
2. `page = GenericXLogRegisterBuffer(state, buffer, flags)` — register a buffer to be modified within the current generic WAL record. This function returns a pointer to a temporary copy of the buffer's page, where modifications should be made. (Do not modify the buffer's contents directly.) The third argument is a bitmask of flags applicable to the operation. Currently the only such flag is `GENERIC_XLOG_FULL_IMAGE`, which indicates that a full-page image rather than a delta update should be included in the WAL record. Typically this flag would be set if the page is new or has been rewritten completely. `GenericXLogRegisterBuffer` can be repeated if the WAL-logged action needs to modify multiple pages.
3. Apply modifications to the page images obtained in the previous step.
4. `GenericXLogFinish(state)` — apply the changes to the buffers and emit the generic WAL record.

WAL record construction can be canceled between any of the above steps by calling `GenericXLogAbort(state)`. This will discard all changes to the page image copies.

Please note the following points when using the generic WAL record facility:

- No direct modifications of buffers are allowed! All modifications must be done in copies acquired from `GenericXLogRegisterBuffer()`. In other words, code that makes generic WAL records should never call `BufferGetPage()` for itself. However, it remains the caller’s responsibility to pin/umpin and lock/unlock the buffers at appropriate times. Exclusive lock must be held on each target buffer from before `GenericXLogRegisterBuffer()` until after `GenericXLogFinish()`.
- Registrations of buffers (step 2) and modifications of page images (step 3) can be mixed freely, i.e., both steps may be repeated in any sequence. Keep in mind that buffers should be registered in the same order in which locks are to be obtained on them during replay.
- The maximum number of buffers that can be registered for a generic WAL record is `MAX_GENERIC_XLOG_PAGES`. An error will be thrown if this limit is exceeded.
- Generic WAL assumes that the pages to be modified have standard layout, and in particular that there is no useful data between `pd_lower` and `pd_upper`.
- Since you are modifying copies of buffer pages, `GenericXLogStart()` does not start a critical section. Thus, you can safely do memory allocation, error throwing, etc. between `GenericXLogStart()` and `GenericXLogFinish()`. The only actual critical section is present...
inside GenericXLogFinish(). There is no need to worry about calling GenericXLogAbort() during an error exit, either.

- GenericXLogFinish() takes care of marking buffers dirty and setting their LSNs. You do not need to do this explicitly.

- For unlogged relations, everything works the same except that no actual WAL record is emitted. Thus, you typically do not need to do any explicit checks for unlogged relations.

- The generic WAL redo function will acquire exclusive locks to buffers in the same order as they were registered. After redoing all changes, the locks will be released in the same order.

- If GENERIC_XLOG_FULL_IMAGE is not specified for a registered buffer, the generic WAL record contains a delta between the old and the new page images. This delta is based on byte-by-byte comparison. This is not very compact for the case of moving data within a page, and might be improved in the future.
Chapter 61. GiST Indexes

61.1. Introduction

GiST stands for Generalized Search Tree. It is a balanced, tree-structured access method, that acts as a base template in which to implement arbitrary indexing schemes. B-trees, R-trees and many other indexing schemes can be implemented in GiST.

One advantage of GiST is that it allows the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from the University of California at Berkeley’s GiST Indexing Project web site\(^1\) and Marcel Kornacker’s thesis, Access Methods for Next-Generation Database Systems\(^2\). The GiST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site\(^3\).

61.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GiST operator classes shown in Table 61-1. (Some of the optional modules described in Appendix F provide additional GiST operator classes.)

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
<th>Ordering Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt;</td>
<td>&amp;&gt;&gt; &gt;&gt;</td>
</tr>
<tr>
<td>circle_ops</td>
<td>circle</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt;</td>
<td>&amp;&gt;&gt; &gt;&gt;</td>
</tr>
<tr>
<td>inet_ops</td>
<td>inet, cidr</td>
<td>&amp;&amp; &gt;&gt; &gt;&gt; = &gt; = &lt;&gt;</td>
<td>&lt;&lt; &lt;&lt; &lt;&lt; = &lt; &lt; =</td>
</tr>
<tr>
<td>point_ops</td>
<td>point</td>
<td>&gt;&gt; ^ &lt;&lt; &lt; &lt; &lt; @</td>
<td>^ ~ =</td>
</tr>
<tr>
<td>poly_ops</td>
<td>polygon</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &amp;&lt;&lt;</td>
<td>&amp;&gt;&gt; &gt;&gt;</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&amp;&amp; &amp;&gt; &amp;&lt; &gt;&gt; &lt;&lt; &lt;</td>
<td>- - =</td>
</tr>
<tr>
<td>tsquery_ops</td>
<td>tsquery</td>
<td>&lt; @ &gt;</td>
<td></td>
</tr>
<tr>
<td>tsvector_ops</td>
<td>tsvector</td>
<td>@ @</td>
<td></td>
</tr>
</tbody>
</table>

1. http://gist.cs.berkeley.edu/
For historical reasons, the inet_ops operator class is not the default class for types inet and cidr. To use it, mention the class name in CREATE INDEX, for example:

```
CREATE INDEX ON my_table USING GIST (my_inet_column inet_ops);
```

### 61.3. Extensibility

Traditionally, implementing a new index access method meant a lot of difficult work. It was necessary to understand the inner workings of the database, such as the lock manager and Write-Ahead Log. The GiST interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GiST layer itself takes care of concurrency, logging and searching the tree structure.

This extensibility should not be confused with the extensibility of the other standard search trees in terms of the data they can handle. For example, PostgreSQL supports extensible B-trees and hash indexes. That means that you can use PostgreSQL to build a B-tree or hash over any data type you want. But B-trees only support range predicates (\(<\), \(\leq\), \(>\)), and hash indexes only support equality queries.

So if you index, say, an image collection with a PostgreSQL B-tree, you can only issue queries such as “is imagex equal to imagey”, “is imagex less than imagey” and “is imagex greater than imagey”. Depending on how you define “equals”, “less than” and “greater than” in this context, this could be useful. However, by using a GiST based index, you could create ways to ask domain-specific questions, perhaps “find all images of horses” or “find all over-exposed images”.

All it takes to get a GiST access method up and running is to implement several user-defined methods, which define the behavior of keys in the tree. Of course these methods have to be pretty fancy to support fancy queries, but for all the standard queries (B-trees, R-trees, etc.) they’re relatively straightforward. In short, GiST combines extensibility along with generality, code reuse, and a clean interface.

There are seven methods that an index operator class for GiST must provide, and two that are optional. Correctness of the index is ensured by proper implementation of the `same`, `consistent` and `union` methods, while efficiency (size and speed) of the index will depend on the `penalty` and `picksplit` methods. The remaining two basic methods are `compress` and `decompress`, which allow an index to have internal tree data of a different type than the data it indexes. The leaves are to be of the indexed data type, while the other tree nodes can be of any C struct (but you still have to follow PostgreSQL data type rules here, see about `varlena` for variable sized data). If the tree’s internal data type exists at the SQL level, the `STORAGE` option of the `CREATE OPERATOR CLASS` command can be used. The optional eighth method is `distance`, which is needed if the operator class wishes to support ordered scans (nearest-neighbor searches). The optional ninth method `fetch` is needed if the operator class wishes to support index-only scans.

#### consistent

Given an index entry \(p\) and a query value \(q\), this function determines whether the index entry is "consistent" with the query; that is, could the predicate \(\text{"indexed_column indexable_operator q"}\) be true for any row represented by the index entry? For a leaf index entry this is equivalent to testing the indexable condition, while for an internal tree node this determines whether it is necessary to scan the subtree of the index represented by the tree node. When the result is `true`, a `recheck` flag must also be returned. This indicates whether the predicate is certainly true or only possibly true. If `recheck = false` then the index has tested
the predicate condition exactly, whereas if \texttt{recheck} = \texttt{true} the row is only a candidate match. In that case the system will automatically evaluate the \texttt{indexable_operator} against the actual row value to see if it is really a match. This convention allows GiST to support both lossless and lossy index structures.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_consistent(internal, data_type, smallint, oid, internal)
RETURNS bool
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_consistent);

Datum
my_consistent(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
bool *recheck = (bool *) PG_GETARG_POINTER(4);
data_type *key = DatumGetDataType(entry->key);
bool retval;

/*
 * determine return value as a function of strategy, key and query.
*
 * Use GIST_LEAF(entry) to know where you’re called in the index tree,
 * which comes handy when supporting the = operator for example (you could
 * check for non empty union() in non-leaf nodes and equality in leaf
 * nodes).
 */

*recheck = true; /* or false if check is exact */

PG_RETURN_BOOL(retval);
}
```

Here, \texttt{key} is an element in the index and \texttt{query} the value being looked up in the index. The \texttt{StrategyNumber} parameter indicates which operator of your operator class is being applied — it matches one of the operator numbers in the \texttt{CREATE OPERATOR CLASS} command.

Depending on which operators you have included in the class, the data type of \texttt{query} could vary with the operator, since it will be whatever type is on the righthand side of the operator, which might be different from the indexed data type appearing on the lefthand side. (The above code skeleton assumes that only one type is possible; if not, fetching the \texttt{query} argument value would have to depend on the operator.) It is recommended that the SQL declaration of the \texttt{consistent} function use the opclass’s indexed data type for the \texttt{query} argument, even though the actual type might be something else depending on the operator.

`union`

This method consolidates information in the tree. Given a set of entries, this function generates a new index entry that represents all the given entries.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_union(internal, internal)
RETURNS storage_type
```
Chapter 61. GiST Indexes

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_union);

Datum
my_union(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GISTENTRY *ent = entryvec->vector;
    data_type *out,
        *tmp,
        *old;
    int      numranges,
            i = 0;

    numranges = entryvec->n;
    tmp = DatumGetDataType(ent[0].key);
    out = tmp;

    if (numranges == 1)
        { out = data_type_deep_copy(tmp);    
          PG_RETURN_DATA_TYPE_P(out);         }

    for (i = 1; i < numranges; i++)  
        { old = out;
          tmp = DatumGetDataType(ent[i].key);
          out = my_union_implementation(out, tmp);
        }

    PG_RETURN_DATA_TYPE_P(out);
}
```

As you can see, in this skeleton we’re dealing with a data type where \( \text{union}(X, Y, Z) = \text{union}(\text{union}(X, Y), Z) \). It’s easy enough to support data types where this is not the case, by implementing the proper union algorithm in this GiST support method.

The result of the \texttt{union} function must be a value of the index’s storage type, whatever that is (it might or might not be different from the indexed column’s type). The \texttt{union} function should return a pointer to newly \texttt{palloc}()ed memory. You can’t just return the input value as-is, even if there is no type change.

As shown above, the \texttt{union} function’s first internal argument is actually a \texttt{GistEntryVector} pointer. The second argument is a pointer to an integer variable, which can be ignored. (It used to be required that the \texttt{union} function store the size of its result value into that variable, but this is no longer necessary.)

\texttt{compress}

Converts the data item into a format suitable for physical storage in an index page.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_compress(internal)
RETURNS internal
```
Chapter 61. GiST Indexes

As 'MODULE_PATHNAME'
LANGUAGE C STRICT;

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_compress);

Datum
my_compress(PG_FUNCTION_ARGS)
{
    GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *retval;

    if (entry->leafkey)
    {
        /* replace entry->key with a compressed version */
        compressed_data_type *compressed_data = palloc(sizeof(compressed_data_type));

        /* fill *compressed_data from entry->key ... */
        retval = palloc(sizeof(GISTENTRY));
        gistentryinit(*retval, PointerGetDatum(compressed_data),
                      entry->rel, entry->page, entry->offset, FALSE);
    }
    else
    {
        /* typically we needn’t do anything with non-leaf entries */
        retval = entry;
    }

    PG_RETURN_POINTER(retval);
}
```

You have to adapt `compressed_data_type` to the specific type you’re converting to in order to compress your leaf nodes, of course.

decompress

The reverse of the `compress` method. Converts the index representation of the data item into a format that can be manipulated by the other GiST methods in the operator class.

The SQL declaration of the function must look like this:

```sql
CREATE OR REPLACE FUNCTION my_decompress(internal) RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_decompress);

Datum
my_decompress(PG_FUNCTION_ARGS)
{
    PG_RETURN_POINTER(PG_GETARG_POINTER(0));
}
```

The above skeleton is suitable for the case where no decompression is needed.
penalty

Returns a value indicating the “cost” of inserting the new entry into a particular branch of the tree. Items will be inserted down the path of least penalty in the tree. Values returned by penalty should be non-negative. If a negative value is returned, it will be treated as zero.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_penalty(internal, internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT; -- in some cases penalty functions need not be strict
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_penalty);

Datum

my_penalty(PG_FUNCTION_ARGS)
{
    GISTENTRY *origentry = (GISTENTRY *) PG_GETARG_POINTER(0);
    GISTENTRY *newentry = (GISTENTRY *) PG_GETARG_POINTER(1);
    float *penalty = (float *) PG_GETARG_POINTER(2);
    data_type *orig = DatumGetDataType(origentry->key);
    data_type *new = DatumGetDataType(newentry->key);

    *penalty = my_penalty_implementation(orig, new);
    PG_RETURN_POINTER(penalty);
}
```

For historical reasons, the penalty function doesn’t just return a float result; instead it has to store the value at the location indicated by the third argument. The return value per se is ignored, though it’s conventional to pass back the address of that argument.

The penalty function is crucial to good performance of the index. It’ll get used at insertion time to determine which branch to follow when choosing where to add the new entry in the tree. At query time, the more balanced the index, the quicker the lookup.

picksplit

When an index page split is necessary, this function decides which entries on the page are to stay on the old page, and which are to move to the new page.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_picksplit(internal, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```c
PG_FUNCTION_INFO_V1(my_picksplit);

Datum

my_picksplit(PG_FUNCTION_ARGS)
{
    GistEntryVector *entryvec = (GistEntryVector *) PG_GETARG_POINTER(0);
    GIST_SPLITVEC *v = (GIST_SPLITVEC *) PG_GETARG_POINTER(1);
    OffsetNumber maxoff = entryvec->n - 1;
    GISTENTRY *ent = entryvec->vector;
    int i,
       nbytes;
    OffsetNumber *left,
```
*right;
data_type *tmp_union;
data_type *unionL;
data_type *unionR;
GISTENTRY **raw_entryvec;

maxoff = entryvec->n - 1;
nbytes = (maxoff + 1) * sizeof(OffsetNumber);

v->spl_left = (OffsetNumber *) palloc(nbytes);
left = v->spl_left;
v->spl_nleft = 0;

v->spl_right = (OffsetNumber *) palloc(nbytes);
right = v->spl_right;
v->spl_nright = 0;

unionL = NULL;
unionR = NULL;

/* Initialize the raw entry vector. */
raw_entryvec = (GISTENTRY **) malloc(entryvec->n * sizeof(void *));
for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    raw_entryvec[i] = &(entryvec->vector[i]);

for (i = FirstOffsetNumber; i <= maxoff; i = OffsetNumberNext(i))
    {
    int real_index = raw_entryvec[i] - entryvec->vector;

    tmp_union = DatumGetDataType(entryvec->vector[real_index].key);
    Assert(tmp_union != NULL);

    /*
    * Choose where to put the index entries and update unionL and unionR
    * accordingly. Append the entries to either v_spl_left or
    * v_spl_right, and care about the counters.
    */

    if (my_choice_is_left(unionL, curl, unionR, curr))
        {
        if (unionL == NULL)
            unionL = tmp_union;
        else
            unionL = my_union_implementation(unionL, tmp_union);

        *left = real_index;
        ++left;
        ++(v->spl_nleft);
        }
    else
        {
        /*
        * Same on the right
        */
        }
    }
Chapter 61. GiST Indexes

Notice that the `picksplit` function’s result is delivered by modifying the passed-in `v` structure. The return value per se is ignored, though it’s conventional to pass back the address of `v`.

Like `penalty`, the `picksplit` function is crucial to good performance of the index. Designing suitable `penalty` and `picksplit` implementations is where the challenge of implementing well-performing GiST indexes lies.

`same`

Returns true if two index entries are identical, false otherwise. (An “index entry” is a value of the index’s storage type, not necessarily the original indexed column’s type.)

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_same(storage_type, storage_type, internal)
RETURNS internal
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
Datum
my_same(PG_FUNCTION_ARGS)
{
    prefix_range *v1 = PG_GETARG_PREFIX_RANGE_P(0);
    prefix_range *v2 = PG_GETARG_PREFIX_RANGE_P(1);
    bool *result = (bool *) PG_GETARG_POINTER(2);

    *result = my_eq(v1, v2);
    PG_RETURN_POINTER(result);
}
```

For historical reasons, the `same` function doesn’t just return a Boolean result; instead it has to store the flag at the location indicated by the third argument. The return value per se is ignored, though it’s conventional to pass back the address of that argument.

`distance`

Given an index entry `p` and a query value `q`, this function determines the index entry’s “distance” from the query value. This function must be supplied if the operator class contains any ordering operators. A query using the ordering operator will be implemented by returning index entries with the smallest “distance” values first, so the results must be consistent with the operator’s semantics. For a leaf index entry the result just represents the distance to the index entry; for an internal tree node, the result must be the smallest distance that any child entry could have.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_distance(internal, data_type, smallint, oid, internal)
RETURNS float8
AS 'MODULE_PATHNAME'
LANGUAGE C STRICT;
```

And the matching code in the C module could then follow this skeleton:

```
Datum
my_distance(PG_FUNCTION_ARGS)
```
Chapter 61. GiST Indexes

```c
{ 
GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
data_type *query = PG_GETARG_DATA_TYPE_P(1);
StrategyNumber strategy = (StrategyNumber) PG_GETARG_UINT16(2);
/* Oid subtype = PG_GETARG_OID(3); */
/* bool *recheck = (bool *) PG_GETARG_POINTER(4); */
data_type *key = DatumGetDataType(entry->key);
double retval;

/*
 * determine return value as a function of strategy, key and query.
 */
PG_RETURN_FLOAT8(retval);
}
```

The arguments to the `distance` function are identical to the arguments of the `consistent` function.

Some approximation is allowed when determining the distance, so long as the result is never greater than the entry's actual distance. Thus, for example, distance to a bounding box is usually sufficient in geometric applications. For an internal tree node, the distance returned must not be greater than the distance to any of the child nodes. If the returned distance is not exact, the function must set `*recheck` to true. (This is not necessary for internal tree nodes; for them, the calculation is always assumed to be inexact.) In this case the executor will calculate the accurate distance after fetching the tuple from the heap, and reorder the tuples if necessary.

If the distance function returns `*recheck = true` for any leaf node, the original ordering operator’s return type must be `float8` or `float4`, and the distance function’s result values must be comparable to those of the original ordering operator, since the executor will sort using both distance function results and recalculated ordering-operator results. Otherwise, the distance function’s result values can be any finite `float8` values, so long as the relative order of the result values matches the order returned by the ordering operator. (Infinity and minus infinity are used internally to handle cases such as nulls, so it is not recommended that `distance` functions return these values.)

`fetch` converts the compressed index representation of a data item into the original data type, for index-only scans. The returned data must be an exact, non-lossy copy of the originally indexed value.

The SQL declaration of the function must look like this:

```
CREATE OR REPLACE FUNCTION my_fetch(internal) 
RETURNS internal 
AS 'MODULE_PATHNAME' 
LANGUAGE C STRICT;
```

The argument is a pointer to a `GISTENTRY` struct. On entry, its `key` field contains a non-NULL leaf datum in compressed form. The return value is another `GISTENTRY` struct, whose `key` field contains the same datum in its original, uncompressed form. If the opclass's `compress` function does nothing for leaf entries, the `fetch` method can return the argument as-is.

The matching code in the C module could then follow this skeleton:

```
PG_FUNCTION_INFO_V1(my_fetch);
```

```c
Datum
my_fetch(PG_FUNCTION_ARGS)
{
```
Chapter 61. GiST Indexes

GISTENTRY *entry = (GISTENTRY *) PG_GETARG_POINTER(0);
input_data_type *in = DatumGetP(entry->key);
fetched_data_type *fetched_data;
GISTENTRY *retval;

retval = palloc(sizeof(GISTENTRY));
fetched_data = palloc(sizeof(fetched_data_type));

/* Convert 'fetched_data' into a Datum of the original datatype. */
/* fill *retval from fetch_data. */
gistentryinit(*retval, PointerGetDatum(converted_datum),
    entry->rel, entry->page, entry->offset, FALSE);
PG_RETURN_POINTER(retval);
}

If the compress method is lossy for leaf entries, the operator class cannot support index-only scans, and must not define a fetch function.

All the GiST support methods are normally called in short-lived memory contexts; that is, CurrentMemoryContext will get reset after each tuple is processed. It is therefore not very important to worry about pfree’ing everything you palloc. However, in some cases it’s useful for a support method to cache data across repeated calls. To do that, allocate the longer-lived data in fcinfo->flinfo->fn_mcxt, and keep a pointer to it in fcinfo->flinfo->fn_extra. Such data will survive for the life of the index operation (e.g., a single GiST index scan, index build, or index tuple insertion). Be careful to pfree the previous value when replacing a fn_extra value, or the leak will accumulate for the duration of the operation.

61.4. Implementation

61.4.1. GiST buffering build

Building large GiST indexes by simply inserting all the tuples tends to be slow, because if the index tuples are scattered across the index and the index is large enough to not fit in cache, the insertions need to perform a lot of random I/O. Beginning in version 9.2, PostgreSQL supports a more efficient method to build GiST indexes based on buffering, which can dramatically reduce the number of random I/Os needed for non-ordered data sets. For well-ordered data sets the benefit is smaller or non-existent, because only a small number of pages receive new tuples at a time, and those pages fit in cache even if the index as whole does not.

However, buffering index build needs to call the penalty function more often, which consumes some extra CPU resources. Also, the buffers used in the buffering build need temporary disk space, up to the size of the resulting index. Buffering can also influence the quality of the resulting index, in both positive and negative directions. That influence depends on various factors, like the distribution of the input data and the operator class implementation.

By default, a GiST index build switches to the buffering method when the index size reaches effective_cache_size. It can be manually turned on or off by the buffering parameter to the CREATE INDEX command. The default behavior is good for most cases, but turning buffering off might speed up the build somewhat if the input data is ordered.
61.5. Examples

The PostgreSQL source distribution includes several examples of index methods implemented using GiST. The core system currently provides text search support (indexing for \textit{tsvector} and \textit{tsquery}) as well as R-Tree equivalent functionality for some of the built-in geometric data types (see \texttt{src/backend/access/gist/gistproc.c}). The following contrib modules also contain GiST operator classes:

- \texttt{btree gist}
  - B-tree equivalent functionality for several data types
- \texttt{cube}
  - Indexing for multidimensional cubes
- \texttt{hstore}
  - Module for storing (key, value) pairs
- \texttt{intarray}
  - RD-Tree for one-dimensional array of int4 values
- \texttt{ltree}
  - Indexing for tree-like structures
- \texttt{pg_trgm}
  - Text similarity using trigram matching
- \texttt{seg}
  - Indexing for “float ranges”
Chapter 62. SP-GiST Indexes

62.1. Introduction

SP-GiST is an abbreviation for space-partitioned GiST. SP-GiST supports partitioned search trees, which facilitate development of a wide range of different non-balanced data structures, such as quad-trees, k-d trees, and radix trees (tries). The common feature of these structures is that they repeatedly divide the search space into partitions that need not be of equal size. Searches that are well matched to the partitioning rule can be very fast.

These popular data structures were originally developed for in-memory usage. In main memory, they are usually designed as a set of dynamically allocated nodes linked by pointers. This is not suitable for direct storing on disk, since these chains of pointers can be rather long which would require too many disk accesses. In contrast, disk-based data structures should have a high fanout to minimize I/O. The challenge addressed by SP-GiST is to map search tree nodes to disk pages in such a way that a search need access only a few disk pages, even if it traverses many nodes.

Like GiST, SP-GiST is meant to allow the development of custom data types with the appropriate access methods, by an expert in the domain of the data type, rather than a database expert.

Some of the information here is derived from Purdue University's SP-GiST Indexing Project web site\(^1\). The SP-GIST implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bartunov, and there is more information on their web site\(^2\).

62.2. Built-in Operator Classes

The core PostgreSQL distribution includes the SP-GiST operator classes shown in Table 62-1.

<table>
<thead>
<tr>
<th>Name</th>
<th>Indexed Data Type</th>
<th>Indexable Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td>kd_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;&lt;@ ^&gt;&gt; ^~</td>
</tr>
<tr>
<td>quad_point_ops</td>
<td>point</td>
<td>&lt;&lt; &lt;&lt;@ ^&gt;&gt; ^~</td>
</tr>
<tr>
<td>range_ops</td>
<td>any range type</td>
<td>&amp;&amp; &amp;&lt;&lt; @&gt; &gt;</td>
</tr>
<tr>
<td>box_ops</td>
<td>box</td>
<td>&lt;&lt; &amp;&amp; &amp;@ &gt; &gt;</td>
</tr>
<tr>
<td>text_ops</td>
<td>text</td>
<td>&lt;= = &gt; &gt;</td>
</tr>
</tbody>
</table>

Of the two operator classes for type point, quad_point_ops is the default. kd_point_ops supports the same operators but uses a different index data structure which may offer better performance in some applications.

1. \(\) http://www.cs.purdue.edu/spgist/
2. \(\) http://www.sai.msu.su/~megera/wiki/spgist_dev
62.3. Extensibility

SP-GiST offers an interface with a high level of abstraction, requiring the access method developer to implement only methods specific to a given data type. The SP-GiST core is responsible for efficient disk mapping and searching the tree structure. It also takes care of concurrency and logging considerations.

Leaf tuples of an SP-GiST tree contain values of the same data type as the indexed column. Leaf tuples at the root level will always contain the original indexed data value, but leaf tuples at lower levels might contain only a compressed representation, such as a suffix. In that case the operator class support functions must be able to reconstruct the original value using information accumulated from the inner tuples that are passed through to reach the leaf level.

Inner tuples are more complex, since they are branching points in the search tree. Each inner tuple contains a set of one or more nodes, which represent groups of similar leaf values. A node contains a downlink that leads either to another, lower-level inner tuple, or to a short list of leaf tuples that all lie on the same index page. Each node normally has a label that describes it; for example, in a radix tree the node label could be the next character of the string value. (Alternatively, an operator class can omit the node labels, if it works with a fixed set of nodes for all inner tuples; see Section 62.4.2.) Optionally, an inner tuple can have a prefix value that describes all its members. In a radix tree this could be the common prefix of the represented strings. The prefix value is not necessarily really a prefix, but can be any data needed by the operator class; for example, in a quad-tree it can store the central point that the four quadrants are measured with respect to. A quad-tree inner tuple would then also contain four nodes corresponding to the quadrants around this central point.

Some tree algorithms require knowledge of level (or depth) of the current tuple, so the SP-GiST core provides the possibility for operator classes to manage level counting while descending the tree. There is also support for incrementally reconstructing the represented value when that is needed, and for passing down additional data (called traverse values) during a tree descent.

Note: The SP-GiST core code takes care of null entries. Although SP-GiST indexes do store entries for nulls in indexed columns, this is hidden from the index operator class code: no null index entries or search conditions will ever be passed to the operator class methods. (It is assumed that SP-GiST operators are strict and so cannot succeed for null values.) Null values are therefore not discussed further here.

There are five user-defined methods that an index operator class for SP-GiST must provide. All five follow the convention of accepting two internal arguments, the first of which is a pointer to a C struct containing input values for the support method, while the second argument is a pointer to a C struct where output values must be placed. Four of the methods just return void, since all their results appear in the output struct; but leaf_consistent additionally returns a boolean result. The methods must not modify any fields of their input structs. In all cases, the output struct is initialized to zeroes before calling the user-defined method.

The five user-defined methods are:

config

Returns static information about the index implementation, including the data type OIDs of the prefix and node label data types.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_config(internal, internal) RETURNS void ...
```
Chapter 62. SP-GiST Indexes

The first argument is a pointer to a spgConfigIn C struct, containing input data for the function. The second argument is a pointer to a spgConfigOut C struct, which the function must fill with result data.

```c
typedef struct spgConfigIn
{
    Oid attType;  /* Data type to be indexed */
} spgConfigIn;

typedef struct spgConfigOut
{
    Oid prefixType;  /* Data type of inner-tuple prefixes */
    Oid labelType;  /* Data type of inner-tuple node labels */
    bool canReturnData;  /* Opclass can reconstruct original data */
    bool longValuesOK;  /* Opclass can cope with values > 1 page */
} spgConfigOut;
```

attType is passed in order to support polymorphic index operator classes; for ordinary fixed-data-type operator classes, it will always have the same value and so can be ignored.

For operator classes that do not use prefixes, prefixType can be set to VOIDOID. Likewise, for operator classes that do not use node labels, labelType can be set to VOIDOID. canReturnData should be set true if the operator class is capable of reconstructing the originally-supplied index value. longValuesOK should be set true only when the attType is of variable length and the operator class is capable of segmenting long values by repeated suffixing (see Section 62.4.1).

choose

Chooses a method for inserting a new value into an inner tuple.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_choose(internal, internal) RETURNS void ...
```

The first argument is a pointer to a spgChooseIn C struct, containing input data for the function. The second argument is a pointer to a spgChooseOut C struct, which the function must fill with result data.

```c
typedef struct spgChooseIn
{
    Datum datum;          /* original datum to be indexed */
    Datum leafDatum;      /* current datum to be stored at leaf */
    int level;            /* current level (counting from zero) */
    /* Data from current inner tuple */
    bool allTheSame;      /* tuple is marked all-the-same? */
    bool hasPrefix;       /* tuple has a prefix? */
    Datum prefixDatum;    /* if so, the prefix value */
    int nNodes;           /* number of nodes in the inner tuple */
    Datum *nodeLabels;    /* node label values (NULL if none) */
} spgChooseIn;

typedef enum spgChooseResultType
{
    spgMatchNode = 1,  /* descend into existing node */
    spgAddNode,        /* add a node to the inner tuple */
    spgSplitTuple      /* split inner tuple (change its prefix) */
} spgChooseResultType;

typedef struct spgChooseOut
```
Chapter 62. SP-GiST Indexes

```c
spgChooseResultType resultType; /* action code, see above */
union
{
    struct /* results for spgMatchNode */
    {
        int nodeN;  /* descend to this node (index from 0) */
        int levelAdd;  /* increment level by this much */
        Datum restDatum;  /* new leaf datum */
    } matchNode;

    struct /* results for spgAddNode */
    {
        Datum nodeLabel;  /* new node’s label */
        int nodeN;  /* where to insert it (index from 0) */
    } addNode;

    struct /* results for spgSplitTuple */
    {
        /* Info to form new inner tuple with one node */
        bool prefixHasPrefix;  /* tuple should have a prefix? */
        Datum prefixPrefixDatum;  /* if so, its value */
        Datum nodeLabel;  /* node’s label */

        /* Info to form new lower-level inner tuple with all old nodes */
        bool postfixHasPrefix;  /* tuple should have a prefix? */
        Datum postfixPrefixDatum;  /* if so, its value */
    } splitTuple;
}
result;
}
```

datum is the original datum that was to be inserted into the index. leafDatum is initially the same as datum, but can change at lower levels of the tree if the choose or picksplit methods change it. When the insertion search reaches a leaf page, the current value of leafDatum is what will be stored in the newly created leaf tuple. level is the current inner tuple’s level, starting at zero for the root level. allTheSame is true if the current inner tuple is marked as containing multiple equivalent nodes (see Section 62.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if there are no labels.

The choose function can determine either that the new value matches one of the existing child nodes, or that a new child node must be added, or that the new value is inconsistent with the tuple prefix and so the inner tuple must be split to create a less restrictive prefix.

If the new value matches one of the existing child nodes, set resultType to spgMatchNode. Set nodeN to the index (from zero) of that node in the node array. Set levelAdd to the increment in level caused by descending through that node, or leave it as zero if the operator class does not use levels. Set restDatum to equal datum if the operator class does not modify datums from one level to the next, or otherwise set it to the modified value to be used as leafDatum at the next level.

If a new child node must be added, set resultType to spgAddNode. Set nodeLabel to the label to be used for the new node, and set nodeN to the index (from zero) at which to insert the node in the node array. After the node has been added, the choose function will be called again with the modified inner tuple; that call should result in an spgMatchNode result.

If the new value is inconsistent with the tuple prefix, set resultType to spgSplitTuple. This action moves all the existing nodes into a new lower-level inner tuple, and replaces the existing inner tuple with a tuple having a single node that links to the new lower-level inner tuple. Set
prefixHasPrefix to indicate whether the new upper tuple should have a prefix, and if so set prefixPrefixDatum to the prefix value. This new prefix value must be sufficiently less restrictive than the original to accept the new value to be indexed, and it should be no longer than the original prefix. Set nodeLabel to the label to be used for the node that will point to the new lower-level inner tuple. Set postfixHasPrefix to indicate whether the new lower-level inner tuple should have a prefix, and if so set postfixPrefixDatum to the prefix value. The combination of these two prefixes and the additional label must have the same meaning as the original prefix, because there is no opportunity to alter the node labels that are moved to the new lower-level tuple, nor to change any child index entries. After the node has been split, the choose function will be called again with the replacement inner tuple. That call will usually result in an spgAddNode result, since presumably the node label added in the split step will not match the new value; so after that, there will be a third call that finally returns spgMatchNode and allows the insertion to descend to the leaf level.

picksplit

Decides how to create a new inner tuple over a set of leaf tuples.

The SQL declaration of the function must look like this:

CREATE FUNCTION my_picksplit(internal, internal) RETURNS void ...  

The first argument is a pointer to a spgPickSplitIn C struct, containing input data for the function. The second argument is a pointer to a spgPickSplitOut C struct, which the function must fill with result data.

typedef struct spgPickSplitIn
{
  int nTuples;    /* number of leaf tuples */
  Datum *datums; /* their datums (array of length nTuples) */
  int level;     /* current level (counting from zero) */
} spgPickSplitIn;

typedef struct spgPickSplitOut
{
  bool hasPrefix; /* new inner tuple should have a prefix? */
  Datum prefixDatum; /* if so, its value */
  int nNodes; /* number of nodes for new inner tuple */
  Datum *nodeLabels; /* their labels (or NULL for no labels) */
  int *mapTuplesToNodes; /* node index for each leaf tuple */
  Datum *leafTupleDatums; /* datum to store in each new leaf tuple */
} spgPickSplitOut;

nTuples is the number of leaf tuples provided. datums is an array of their datum values. level is the current level that all the leaf tuples share, which will become the level of the new inner tuple.

Set hasPrefix to indicate whether the new inner tuple should have a prefix, and if so set prefixDatum to the prefix value. Set nNodes to indicate the number of nodes that the new inner tuple will contain, and set nodeLabels to an array of their label values, or to NULL if node labels are not required. Set mapTuplesToNodes to an array that gives the index (from zero) of the node that each leaf tuple should be assigned to. Set leafTupleDatums to an array of the values to be stored in the new leaf tuples (these will be the same as the input datums if the operator class does not modify datums from one level to the next). Note that the picksplit function is responsible for palloc'ing the nodeLabels, mapTuplesToNodes and leafTupleDatums arrays.
If more than one leaf tuple is supplied, it is expected that the `picksplit` function will classify them into more than one node; otherwise it is not possible to split the leaf tuples across multiple pages, which is the ultimate purpose of this operation. Therefore, if the `picksplit` function ends up placing all the leaf tuples in the same node, the core SP-GiST code will override that decision and generate an inner tuple in which the leaf tuples are assigned at random to several identically-labeled nodes. Such a tuple is marked `allTheSame` to signify that this has happened. The `choose` and `inner_consistent` functions must take suitable care with such inner tuples. See Section 62.4.3 for more information.

`picksplit` can be applied to a single leaf tuple only in the case that the `config` function set `longValuesOK` to true and a larger-than-a-page input value has been supplied. In this case the point of the operation is to strip off a prefix and produce a new, shorter leaf datum value. The call will be repeated until a leaf datum short enough to fit on a page has been produced. See Section 62.4.1 for more information.

`inner_consistent` returns set of nodes (branches) to follow during tree search.

The SQL declaration of the function must look like this:

```sql
CREATE FUNCTION my_inner_consistent(internal, internal) RETURNS void ...
```

The first argument is a pointer to a `spgInnerConsistentIn` C struct, containing input data for the function. The second argument is a pointer to a `spgInnerConsistentOut` C struct, which the function must fill with result data.

```c
typedef struct spgInnerConsistentIn {
    ScanKey scankeys; /* array of operators and comparison values */
    int nkeys; /* length of array */
    Datum reconstructedValue; /* value reconstructed at parent */
    void *traversalValue; /* opclass-specific traverse value */
    MemoryContext traversalMemoryContext; /* put new traverse values here */
    int level; /* current level (counting from zero) */
    bool returnData; /* original data must be returned? */
    /* Data from current inner tuple */
    bool allTheSame; /* tuple is marked all-the-same? */
    bool hasPrefix; /* tuple has a prefix? */
    Datum prefixDatum; /* if so, the prefix value */
    int nNodes; /* number of nodes in the inner tuple */
    Datum *nodeLabels; /* node label values (NULL if none) */
} spgInnerConsistentIn;

typedef struct spgInnerConsistentOut {
    int nNodes; /* number of child nodes to be visited */
    int *nodeNumbers; /* their indexes in the node array */
    int *levelAdds; /* increment level by this much for each */
    Datum *reconstructedValues; /* associated reconstructed values */
    void **traversalValues; /* opclass-specific traverse values */
} spgInnerConsistentOut;
```

The array `scankeys`, of length `nkeys`, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them are interesting. (Note that `nkeys = 0` implies that all index entries satisfy the query.) Usually the consistent function only cares about the `sk_strategy` and `sk_argument` fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check...
sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. traversalValue is a pointer to any traverse data passed down from the previous call of inner_consistent on the parent index tuple, or NULL at the root level. traversalMemoryContext is the memory context in which to store output traverse values (see below). level is the current inner tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. allTheSame is true if the current inner tuple is marked “all-the-same”; in this case all the nodes have the same label (if any) and so either all or none of them match the query (see Section 62.4.3). hasPrefix is true if the current inner tuple contains a prefix; if so, prefixDatum is its value. nNodes is the number of child nodes contained in the inner tuple, and nodeLabels is an array of their label values, or NULL if the nodes do not have labels.

nNodes must be set to the number of child nodes that need to be visited by the search, and nodeNumbers must be set to an array of their indexes. If the operator class keeps track of levels, set levelAdds to an array of the level increments required when descending to each node to be visited. (Often these increments will be the same for all the nodes, but that’s not necessarily so, so an array is used.) If value reconstruction is needed, set reconstructedValues to an array of the values reconstructed for each child node to be visited; otherwise, leave reconstructedValues as NULL. If it is desired to pass down additional out-of-band information (“traverse values”) to lower levels of the tree search, set traversalValues to an array of the appropriate traverse values, one for each child node to be visited; otherwise, leave traversalValues as NULL. Note that the inner_consistent function is responsible for palloc’ing the nodeNumbers, levelAdds, reconstructedValues, and traversalValues arrays in the current memory context. However, any output traverse values pointed to by the traversalValues array should be allocated in traversalMemoryContext. Each traverse value must be a single palloc’d chunk.

leaf_consistent

Returns true if a leaf tuple satisfies a query.

The SQL declaration of the function must look like this:

```
CREATE FUNCTION my_leaf_consistent(internal, internal) RETURNS bool ...
```

The first argument is a pointer to a spgLeafConsistentIn C struct, containing input data for the function. The second argument is a pointer to a spgLeafConsistentOut C struct, which the function must fill with result data.

typedef struct spgLeafConsistentIn
{
    ScanKey scankeys; /* array of operators and comparison values */
    int nkeys; /* length of array */
    void *traversalValue; /* opclass-specific traverse value */
    Datum reconstructedValue; /* value reconstructed at parent */
    int level; /* current level (counting from zero) */
    bool returnData; /* original data must be returned? */
    Datum leafDatum; /* datum in leaf tuple */
} spgLeafConsistentIn;

typedef struct spgLeafConsistentOut
{
    Datum leafValue; /* reconstructed original data, if any */
Chapter 62. SP-GiST Indexes

bool recheck; /* set true if operator must be rechecked */
}

spgLeafConsistentOut;

The array scankeys, of length nkeys, describes the index search condition(s). These conditions are combined with AND — only index entries that satisfy all of them satisfy the query. (Note that nkeys = 0 implies that all index entries satisfy the query.) Usually the consistent function only cares about the sk_strategy and sk_argument fields of each array entry, which respectively give the indexable operator and comparison value. In particular it is not necessary to check sk_flags to see if the comparison value is NULL, because the SP-GiST core code will filter out such conditions. reconstructedValue is the value reconstructed for the parent tuple; it is (Datum) 0 at the root level or if the inner_consistent function did not provide a value at the parent level. traversalValue is a pointer to any traverse data passed down from the previous call of inner_consistent on the parent index tuple, or NULL at the root level. level is the current leaf tuple’s level, starting at zero for the root level. returnData is true if reconstructed data is required for this query; this will only be so if the config function asserted canReturnData. leafDatum is the key value stored in the current leaf tuple.

The function must return true if the leaf tuple matches the query, or false if not. In the true case, if returnData is true then leafValue must be set to the value originally supplied to be indexed for this leaf tuple. Also, recheck may be set to true if the match is uncertain and so the operator(s) must be re-applied to the actual heap tuple to verify the match.

All the SP-GiST support methods are normally called in a short-lived memory context; that is, CurrentMemoryContext will be reset after processing of each tuple. It is therefore not very important to worry about pfree’ing everything you palloc. (The config method is an exception: it should try to avoid leaking memory. But usually the config method need do nothing but assign constants into the passed parameter struct.)

If the indexed column is of a collatable data type, the index collation will be passed to all the support methods, using the standard PG_GET_COLLATION() mechanism.

62.4. Implementation

This section covers implementation details and other tricks that are useful for implementers of SP-GiST operator classes to know.

62.4.1. SP-GiST Limits

Individual leaf tuples and inner tuples must fit on a single index page (8kB by default). Therefore, when indexing values of variable-length data types, long values can only be supported by methods such as radix trees, in which each level of the tree includes a prefix that is short enough to fit on a page, and the final leaf level includes a suffix also short enough to fit on a page. The operator class should set longValuesOK to TRUE only if it is prepared to arrange for this to happen. Otherwise, the SP-GiST core will reject any request to index a value that is too large to fit on an index page.

Likewise, it is the operator class’s responsibility that inner tuples do not grow too large to fit on an index page; this limits the number of child nodes that can be used in one inner tuple, as well as the maximum size of a prefix value.

Another limitation is that when an inner tuple’s node points to a set of leaf tuples, those tuples must all be in the same index page. (This is a design decision to reduce seeking and save space in the links that chain such tuples together.) If the set of leaf tuples grows too large for a page, a split is performed and an intermediate inner tuple is inserted. For this to fix the problem, the new inner tuple must divide
Chapter 62. SP-GiST Indexes

the set of leaf values into more than one node group. If the operator class’s `picksplit` function fails to do that, the SP-GiST core resorts to extraordinary measures described in Section 62.4.3.

62.4.2. SP-GiST Without Node Labels

Some tree algorithms use a fixed set of nodes for each inner tuple; for example, in a quad-tree there are always exactly four nodes corresponding to the four quadrants around the inner tuple’s centroid point. In such a case the code typically works with the nodes by number, and there is no need for explicit node labels. To suppress node labels (and thereby save some space), the `picksplit` function can return NULL for the `nodeLabels` array. This will in turn result in `nodeLabels` being NULL during subsequent calls to `choose` and `inner_consistent`. In principle, node labels could be used for some inner tuples and omitted for others in the same index.

When working with an inner tuple having unlabeled nodes, it is an error for `choose` to return `spgAddNode`, since the set of nodes is supposed to be fixed in such cases. Also, there is no provision for generating an unlabeled node in `spgSplitTuple` actions, since it is expected that an `spgAddNode` action will be needed as well.

62.4.3. “All-the-same” Inner Tuples

The SP-GiST core can override the results of the operator class’s `picksplit` function when `picksplit` fails to divide the supplied leaf values into at least two node categories. When this happens, the new inner tuple is created with multiple nodes that each have the same label (if any) that `picksplit` gave to the one node it did use, and the leaf values are divided at random among these equivalent nodes. The `allTheSame` flag is set on the inner tuple to warn the `choose` and `inner_consistent` functions that the tuple does not have the node set that they might otherwise expect.

When dealing with an `allTheSame` tuple, a `choose` result of `spgMatchNode` is interpreted to mean that the new value can be assigned to any of the equivalent nodes; the core code will ignore the supplied `nodeN` value and descend into one of the nodes at random (so as to keep the tree balanced). It is an error for `choose` to return `spgAddNode`, since that would make the nodes not all equivalent; the `spgSplitTuple` action must be used if the value to be inserted doesn’t match the existing nodes.

When dealing with an `allTheSame` tuple, the `inner_consistent` function should return either all or none of the nodes as targets for continuing the index search, since they are all equivalent. This may or may not require any special-case code, depending on how much the `inner_consistent` function normally assumes about the meaning of the nodes.

62.5. Examples

The PostgreSQL source distribution includes several examples of index operator classes for SP-GiST, as described in Table 62-1. Look into `src/backend/access/spgist/` and `src/backend/utils/adt/` to see the code.
Chapter 63. GIN Indexes

63.1. Introduction

GIN stands for Generalized Inverted Index. GIN is designed for handling cases where the items to be
indexed are composite values, and the queries to be handled by the index need to search for element
values that appear within the composite items. For example, the items could be documents, and the
queries could be searches for documents containing specific words.

We use the word *item* to refer to a composite value that is to be indexed, and the word *key* to refer to
an element value. GIN always stores and searches for keys, not item values per se.

A GIN index stores a set of (key, posting list) pairs, where a *posting list* is a set of row IDs in which
the key occurs. The same row ID can appear in multiple posting lists, since an item can contain more
than one key. Each key value is stored only once, so a GIN index is very compact for cases where the
same key appears many times.

GIN is generalized in the sense that the GIN access method code does not need to know the spec-
cific operations that it accelerates. Instead, it uses custom strategies defined for particular data types.
The strategy defines how keys are extracted from indexed items and query conditions, and how to
determine whether a row that contains some of the key values in a query actually satisfies the query.

One advantage of GIN is that it allows the development of custom data types with the appropriate
access methods, by an expert in the domain of the data type, rather than a database expert. This is
much the same advantage as using GiST.

The GIN implementation in PostgreSQL is primarily maintained by Teodor Sigaev and Oleg Bar-
tunov. There is more information about GIN on their website.

63.2. Built-in Operator Classes

The core PostgreSQL distribution includes the GIN operator classes shown in Table 63-1. (Some of
the optional modules described in Appendix F provide additional GIN operator classes.)

Table 63-1. Built-in GIN Operator Classes

<table>

<td>0 @ 0 @ 0</td>
</tr>
</tbody>
</table>

Of the two operator classes for type jsonb, jsonb_ops is the default. jsonb_path_ops supports fewer operators but offers better performance for those operators. See Section 8.14.4 for details.

63.3. Extensibility

The GIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The GIN layer itself takes care of concurrency, logging and searching the tree structure.

All it takes to get a GIN access method working is to implement a few user-defined methods, which define the behavior of keys in the tree and the relationships between keys, indexed items, and indexable queries. In short, GIN combines extensibility with generality, code reuse, and a clean interface.

There are three methods that an operator class for GIN must provide:

```c
int compare(Datum a, Datum b)
```

Compares two keys (not indexed items!) and returns an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. Null
keys are never passed to this function.

Datum *extractValue(Datum itemValue, int32 *nkeys, bool **nullFlags)

Returns a palloc’d array of keys given an item to be indexed. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the item contains no keys.

Datum *extractQuery(Datum query, int32 *nkeys, StrategyNumber n, bool *pmatch, Pointer **extra_data, bool **nullFlags, int32 *searchMode)

Returns a palloc’d array of keys given a value to be queried; that is, query is the value on the right-hand side of an indexable operator whose left-hand side is the indexed column. n is the strategy number of the operator within the operator class (see Section 36.14.2). Often, extractQuery will need to consult n to determine the data type of query and the method it should use to extract key values. The number of returned keys must be stored into *nkeys. If any of the keys can be null, also palloc an array of *nkeys bool fields, store its address at *nullFlags, and set these null flags as needed. *nullFlags can be left NULL (its initial value) if all keys are non-null. The return value can be NULL if the query contains no keys.

searchMode is an output argument that allows extractQuery to specify details about how the search will be done. If searchMode is set to GIN_SEARCH_MODE_DEFAULT (which is the value it is initialized to before call), only items that match at least one of the returned keys are considered candidate matches. If searchMode is set to GIN_SEARCH_MODE_INCLUDE_EMPTY, then in addition to items containing at least one matching key, items that contain no keys at all are considered candidate matches. (This mode is useful for implementing is-subset-of operators, for example.) If searchMode is set to GIN_SEARCH_MODE_ALL, then all non-null items in the index are considered candidate matches, whether they match any of the returned keys or not. (This mode is much slower than the other two choices, since it requires scanning essentially the entire index, but it may be necessary to implement corner cases correctly. An operator that needs this mode in most cases is probably not a good candidate for a GIN operator class.) The symbols to use for setting this mode are defined in access/gin.h.

pmatch is an output argument for use when partial match is supported. To use it, extractQuery must allocate an array of *nkeys booleans and store its address at *pmatch. Each element of the array should be set to TRUE if the corresponding key requires partial match, FALSE if not. If *pmatch is set to NULL then GIN assumes partial match is not required. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not support partial match.

eextra_data is an output argument that allows extractQuery to pass additional data to the consistent and comparePartial methods. To use it, extractQuery must allocate an array of *nkeys pointers and store its address at *extra_data, then store whatever it wants to into the individual pointers. The variable is initialized to NULL before call, so this argument can simply be ignored by operator classes that do not require extra data. If *extra_data is set, the whole array is passed to the consistent method, and the appropriate element to the comparePartial method.

An operator class must also provide a function to check if an indexed item matches the query. It comes in two flavors, a boolean consistent function, and a ternary triConsistent function. triConsistent covers the functionality of both, so providing triConsistent alone is sufficient. However, if the boolean variant is significantly cheaper to calculate, it can be advantageous to provide both. If only the boolean variant is provided, some optimizations that depend on refuting index items before fetching all the keys are disabled.
bool consistent(bool check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], bool *recheck, Datum queryKeys[], bool nullFlags[])

Returns TRUE if an indexed item satisfies the query operator with strategy number n (or might satisfy it, if the recheck indication is returned). This function does not have direct access to the indexed item’s value, since GIN does not store items explicitly. Rather, what is available is knowledge about which key values extracted from the query appear in a given indexed item. The check array has length nkeys, which is the same as the number of keys previously returned by extractQuery for this query datum. Each element of the check array is TRUE if the indexed item contains the corresponding query key, i.e., if (check[i] == TRUE) the i-th key of the extractQuery result array is present in the indexed item. The original query datum is passed in case the consistent method needs to consult it, and so are the queryKeys[] and nullFlags[] arrays previously returned by extractQuery. extra_data is the extra-data array returned by extractQuery, or NULL if none.

When extractQuery returns a null key in queryKeys[], the corresponding check[] element is TRUE if the indexed item contains a null key; that is, the semantics of check[] are like IS NOT DISTINCT FROM. The consistent function can examine the corresponding nullFlags[] element if it needs to tell the difference between a regular value match and a null match.

On success, *recheck should be set to TRUE if the heap tuple needs to be rechecked against the query operator, or FALSE if the index test is exact. That is, a FALSE return value guarantees that the heap tuple does not match the query; a TRUE return value with *recheck set to FALSE guarantees that the heap tuple does match the query; and a TRUE return value with *recheck set to TRUE means that the heap tuple might match the query, so it needs to be fetched and rechecked by evaluating the query operator directly against the originally indexed item.

GinTernaryValue triConsistent(GinTernaryValue check[], StrategyNumber n, Datum query, int32 nkeys, Pointer extra_data[], Datum queryKeys[], bool nullFlags[])

triConsistent is similar to consistent, but instead of booleans in the check vector, there are three possible values for each key: GIN_TRUE, GIN_FALSE and GIN_MAYBE. GIN_FALSE and GIN_TRUE have the same meaning as regular boolean values, while GIN_MAYBE means that the presence of that key is not known. When GIN_MAYBE values are present, the function should only return GIN_TRUE if the item certainly matches whether or not the index item contains the corresponding query keys. Likewise, the function must return GIN_FALSE only if the item certainly does not match, whether or not it contains the GIN_MAYBE keys. If the result depends on the GIN_MAYBE entries, i.e., the match cannot be confirmed or refuted based on the known query keys, the function must return GIN_MAYBE.

When there are no GIN_MAYBE values in the check vector, a GIN_MAYBE return value is the equivalent of setting the recheck flag in the boolean consistent function.

Optionally, an operator class for GIN can supply the following method:

int comparePartial(Datum partial_key, Datum key, StrategyNumber n, Pointer extra_data)

Compare a partial-match query key to an index key. Returns an integer whose sign indicates the result: less than zero means the index key does not match the query, but the index scan should continue; zero means that the index key does match the query; greater than zero indicates that the index scan should stop because no more matches are possible. The strategy number n of the operator that generated the partial match query is provided, in case its semantics are needed to determine when to end the scan. Also, extra_data is the corresponding element of the extra-data array made by extractQuery, or NULL if none. Null keys are never passed to this function.
Chapter 63. GIN Indexes

To support “partial match” queries, an operator class must provide the comparePartial method, and its extractQuery method must set the pmatch parameter when a partial-match query is encountered. See Section 63.4.2 for details.

The actual data types of the various Datum values mentioned above vary depending on the operator class. The item values passed to extractValue are always of the operator class’s input type, and all key values must be of the class’s STORAGE type. The type of the query argument passed to extractQuery, consistent and triConsistent is whatever is the right-hand input type of the class member operator identified by the strategy number. This need not be the same as the indexed type, so long as key values of the correct type can be extracted from it. However, it is recommended that the SQL declarations of these three support functions use the opclass’s indexed data type for the query argument, even though the actual type might be something else depending on the operator.

63.4. Implementation

Internally, a GIN index contains a B-tree index constructed over keys, where each key is an element of one or more indexed items (a member of an array, for example) and where each tuple in a leaf page contains either a pointer to a B-tree of heap pointers (a “posting tree”), or a simple list of heap pointers (a “posting list”) when the list is small enough to fit into a single index tuple along with the key value.

As of PostgreSQL 9.1, null key values can be included in the index. Also, placeholder nulls are included in the index for indexed items that are null or contain no keys according to extractValue. This allows searches that should find empty items to do so.

Multicolumn GIN indexes are implemented by building a single B-tree over composite values (column number, key value). The key values for different columns can be of different types.

63.4.1. GIN Fast Update Technique

Updating a GIN index tends to be slow because of the intrinsic nature of inverted indexes: inserting or updating one heap row can cause many inserts into the index (one for each key extracted from the indexed item). As of PostgreSQL 8.4, GIN is capable of postponing much of this work by inserting new tuples into a temporary, unsorted list of pending entries. When the table is vacuumed or autoanalyzed, or when gin_clean_pending_list function is called, or if the pending list becomes larger than gin_pending_list_limit, the entries are moved to the main GIN data structure using the same bulk insert techniques used during initial index creation. This greatly improves GIN index update speed, even counting the additional vacuum overhead. Moreover the overhead work can be done by a background process instead of in foreground query processing.

The main disadvantage of this approach is that searches must scan the list of pending entries in addition to searching the regular index, and so a large list of pending entries will slow searches significantly. Another disadvantage is that, while most updates are fast, an update that causes the pending list to become “too large” will incur an immediate cleanup cycle and thus be much slower than other updates. Proper use of autovacuum can minimize both of these problems.

If consistent response time is more important than update speed, use of pending entries can be disabled by turning off the fastupdate storage parameter for a GIN index. See CREATE INDEX for details.
63.4.2. Partial Match Algorithm

GIN can support “partial match” queries, in which the query does not determine an exact match for one or more keys, but the possible matches fall within a reasonably narrow range of key values (within the key sorting order determined by the compare support method). The extractQuery method, instead of returning a key value to be matched exactly, returns a key value that is the lower bound of the range to be searched, and sets the pmatch flag true. The key range is then scanned using the comparePartial method. comparePartial must return zero for a matching index key, less than zero for a non-match that is still within the range to be searched, or greater than zero if the index key is past the range that could match.

63.5. GIN Tips and Tricks

Create vs. insert

Insertion into a GIN index can be slow due to the likelihood of many keys being inserted for each item. So, for bulk insertions into a table it is advisable to drop the GIN index and recreate it after finishing bulk insertion.

As of PostgreSQL 8.4, this advice is less necessary since delayed indexing is used (see Section 63.4.1 for details). But for very large updates it may still be best to drop and recreate the index.

maintenance_work_mem

Build time for a GIN index is very sensitive to the maintenance_work_mem setting; it doesn’t pay to skimp on work memory during index creation.

gin_pending_list_limit

During a series of insertions into an existing GIN index that has fastupdate enabled, the system will clean up the pending-entry list whenever the list grows larger than gin_pending_list_limit. To avoid fluctuations in observed response time, it’s desirable to have pending-list cleanup occur in the background (i.e., via autovacuum). Foreground cleanup operations can be avoided by increasing gin_pending_list_limit or making autovacuum more aggressive. However, enlarging the threshold of the cleanup operation means that if a foreground cleanup does occur, it will take even longer.

gin_pending_list_limit can be overridden for individual GIN indexes by changing storage parameters, and which allows each GIN index to have its own cleanup threshold. For example, it’s possible to increase the threshold only for the GIN index which can be updated heavily, and decrease it otherwise.

gin_fuzzy_search_limit

The primary goal of developing GIN indexes was to create support for highly scalable full-text search in PostgreSQL, and there are often situations when a full-text search returns a very large set of results. Moreover, this often happens when the query contains very frequent words, so that the large result set is not even useful. Since reading many tuples from the disk and sorting them could take a lot of time, this is unacceptable for production. (Note that the index search itself is very fast.)

To facilitate controlled execution of such queries, GIN has a configurable soft upper limit on the number of rows returned: the gin_fuzzy_search_limit configuration parameter. It is set to 0 (meaning no limit) by default. If a non-zero limit is set, then the returned set is a subset of the whole result set, chosen at random.
“Soft” means that the actual number of returned results could differ somewhat from the specified limit, depending on the query and the quality of the system’s random number generator. From experience, values in the thousands (e.g., 5000 — 20000) work well.

### 63.6. Limitations

GIN assumes that indexable operators are strict. This means that `extractValue` will not be called at all on a null item value (instead, a placeholder index entry is created automatically), and `extractQuery` will not be called on a null query value either (instead, the query is presumed to be unsatisfiable). Note however that null key values contained within a non-null composite item or query value are supported.

### 63.7. Examples

The PostgreSQL source distribution includes GIN operator classes for `tsvector` and for one-dimensional arrays of all internal types. Prefix searching in `tsvector` is implemented using the GIN partial match feature. The following `contrib` modules also contain GIN operator classes:

- **btree_gin**
  - B-tree equivalent functionality for several data types
- **hstore**
  - Module for storing (key, value) pairs
- **intarray**
  - Enhanced support for `int[]`
- **pg_trgm**
  - Text similarity using trigram matching
Chapter 64. BRIN Indexes

64.1. Introduction

BRIN stands for Block Range Index. BRIN is designed for handling very large tables in which certain columns have some natural correlation with their physical location within the table. A block range is a group of pages that are physically adjacent in the table; for each block range, some summary info is stored by the index. For example, a table storing a store’s sale orders might have a date column on which each order was placed, and most of the time the entries for earlier orders will appear earlier in the table as well; a table storing a ZIP code column might have all codes for a city grouped together naturally.

BRIN indexes can satisfy queries via regular bitmap index scans, and will return all tuples in all pages within each range if the summary info stored by the index is consistent with the query conditions. The query executor is in charge of rechecking these tuples and discarding those that do not match the query conditions — in other words, these indexes are lossy. Because a BRIN index is very small, scanning the index adds little overhead compared to a sequential scan, but may avoid scanning large parts of the table that are known not to contain matching tuples.

The specific data that a BRIN index will store, as well as the specific queries that the index will be able to satisfy, depend on the operator class selected for each column of the index. Data types having a linear sort order can have operator classes that store the minimum and maximum value within each block range, for instance; geometrical types might store the bounding box for all the objects in the block range.

The size of the block range is determined at index creation time by the pages_per_range storage parameter. The number of index entries will be equal to the size of the relation in pages divided by the selected value for pages_per_range. Therefore, the smaller the number, the larger the index becomes (because of the need to store more index entries), but at the same time the summary data stored can be more precise and more data blocks can be skipped during an index scan.

64.1.1. Index Maintenance

At the time of creation, all existing index pages are scanned and a summary index tuple is created for each range, including the possibly-incomplete range at the end. As new pages are filled with data, page ranges that are already summarized will cause the summary information to be updated with data from the new tuples. When a new page is created that does not fall within the last summarized range, that range does not automatically acquire a summary tuple; those tuples remain unsummarized until a summarization run is invoked later, creating initial summaries. This process can be invoked manually using the brin_summarize_new_values(regclass) function, or automatically when VACUUM processes the table.

64.2. Built-in Operator Classes

The core PostgreSQL distribution includes the BRIN operator classes shown in Table 64-1.
The *minmax* operator classes store the minimum and the maximum values appearing in the indexed column within the range. The *inclusion* operator classes store a value which includes the values in the indexed column within the range.

### Table 64-1. Built-in BRIN Operator Classes

</table>
64.3. Extensibility

The BRIN interface has a high level of abstraction, requiring the access method implementer only to implement the semantics of the data type being accessed. The BRIN layer itself takes care of concurrency, logging and searching the index structure.

All it takes to get a BRIN access method working is to implement a few user-defined methods, which define the behavior of summary values stored in the index and the way they interact with scan keys. In short, BRIN combines extensibility with generality, code reuse, and a clean interface.

There are four methods that an operator class for BRIN must provide:

```c
BrinOpcInfo *opcInfo(Oid type_oid)
```

Returns internal information about the indexed columns’ summary data. The return value must point to a `palloc`d `BrinOpcInfo`, which has this definition:

```c
typedef struct BrinOpcInfo {
    /* Number of columns stored in an index column of this opclass */
    uint16   oi_nstored;

    /* Opaque pointer for the opclass’ private use */
    void *    oi_opaque;

    /* Type cache entries of the stored columns */
    TypeCacheEntry *oi_typcache[ FLEXIBLE_ARRAY_MEMBER ];
} BrinOpcInfo;
```

`BrinOpcInfo.oi_opaque` can be used by the operator class routines to pass information between support procedures during an index scan.

```c
bool consistent(BrinDesc *bdesc, BrinValues *column, ScanKey key)
```

Returns whether the ScanKey is consistent with the given indexed values for a range. The attribute number to use is passed as part of the scan key.

```c
bool addValue(BrinDesc *bdesc, BrinValues *column, Datum newval, bool isnull)
```

Given an index tuple and an indexed value, modifies the indicated attribute of the tuple so that it additionally represents the new value. If any modification was done to the tuple, `true` is returned.

```c
bool unionTuples(BrinDesc *bdesc, BrinValues *a, BrinValues *b)
```

Consolidates two index tuples. Given two index tuples, modifies the indicated attribute of the first of them so that it represents both tuples. The second tuple is not modified.

The core distribution includes support for two types of operator classes: minmax and inclusion. Operator class definitions using them are shipped for in-core data types as appropriate. Additional operator classes can be defined by the user for other data types using equivalent definitions, without having to write any source code; appropriate catalog entries being declared is enough. Note that assumptions about the semantics of operator strategies are embedded in the support procedures’ source code.

Operator classes that implement completely different semantics are also possible, provided implementations of the four main support procedures described above are written. Note that backwards compatibility across major releases is not guaranteed: for example, additional support procedures might be required in later releases.

To write an operator class for a data type that implements a totally ordered set, it is possible to use the minmax support procedures alongside the corresponding operators, as shown in Table 64-2. All operator class members (procedures and operators) are mandatory.
To write an operator class for a complex data type which has values included within another type, it’s possible to use the inclusion support procedures alongside the corresponding operators, as shown in Table 64-3. It requires only a single additional function, which can be written in any language. More functions can be defined for additional functionality. All operators are optional. Some operators require other operators, as shown as dependencies on the table.

---

Chapter 64. BRIN Indexes
Support procedure numbers 1-10 are reserved for the BRIN internal functions, so the SQL level functions start with number 11. Support function number 11 is the main function required to build the index. It should accept two arguments with the same data type as the operator class, and return the union of them. The inclusion operator class can store union values with different data types if it is defined with the \texttt{STORAGE} parameter. The return value of the union function should match the \texttt{STORAGE} data type.

Support procedure numbers 12 and 14 are provided to support irregularities of built-in data types. Procedure number 12 is used to support network addresses from different families which are not mergeable. Procedure number 14 is used to support empty ranges. Procedure number 13 is an optional but recommended one, which allows the new value to be checked before it is passed to the union function. As the BRIN framework can shortcut some operations when the union is not changed, using this function can improve index performance.

Both minmax and inclusion operator classes support cross-data-type operators, though with these the dependencies become more complicated. The minmax operator class requires a full set of operators to be defined with both arguments having the same data type. It allows additional data types to be supported by defining extra sets of operators. Inclusion operator class operator strategies are dependent on another operator strategy as shown in Table 64-3, or the same operator strategy as themselves. They require the dependency operator to be defined with the \texttt{STORAGE} data type as the left-hand-side argument and the other supported data type to be the right-hand-side argument of the supported operator. See \texttt{float4\_minmax\_ops} as an example of minmax, and \texttt{box\_inclusion\_ops} as an example of inclusion.
Chapter 65. Database Physical Storage

This chapter provides an overview of the physical storage format used by PostgreSQL databases.

65.1. Database File Layout

This section describes the storage format at the level of files and directories.

Traditionally, the configuration and data files used by a database cluster are stored together within the cluster’s data directory, commonly referred to as `PGDATA` (after the name of the environment variable that can be used to define it). A common location for `PGDATA` is `/var/lib/pgsql/data`. Multiple clusters, managed by different server instances, can exist on the same machine.

The `PGDATA` directory contains several subdirectories and control files, as shown in Table 65-1. In addition to these required items, the cluster configuration files `postgresql.conf`, `pg_hba.conf`, and `pg_ident.conf` are traditionally stored in `PGDATA`, although it is possible to place them elsewhere.

Table 65-1. Contents of `PGDATA`

<td>A lock file recording the current postmaster process ID (PID), cluster data directory path, postmaster start timestamp, port number, Unix-domain socket directory path (empty on Windows), first valid listen_address (IP address or *, or empty if not listening on TCP), and shared memory segment ID (this file is not present after server shutdown)</td>
</tr>
</tbody>
</table>

For each database in the cluster there is a subdirectory within PGDATA/base, named after the database’s OID in pg_database. This subdirectory is the default location for the database’s files; in particular, its system catalogs are stored there.

Each table and index is stored in a separate file. For ordinary relations, these files are named after the table or index’s filenode number, which can be found in pg_class.relfilenode. But for temporary relations, the file name is of the form tBBB_FFF, where BBB is the backend ID of the backend which created the file, and FFF is the filenode number. In either case, in addition to the main file (a/k/a main fork), each table and index has a free space map (see Section 65.3), which stores information about free space available in the relation. The free space map is stored in a file named with the filenode number plus the suffix _fsm. Tables also have a visibility map, stored in a fork with the suffix _vm, to track which pages are known to have no dead tuples. The visibility map is described further in Section 65.4. Unlogged tables and indexes have a third fork, known as the initialization fork, which is stored in a fork with the suffix _init (see Section 65.5).

Caution

Note that while a table’s filenode often matches its OID, this is not necessarily the case; some operations, like TRUNCATE, REINDEX, CLUSTER and some forms of ALTER TABLE, can change the filenode while preserving the OID. Avoid assuming that filenode and table OID are the same. Also, for certain system catalogs including pg_class itself, pg_class.relfilenode contains zero. The actual filenode number of these catalogs is stored in a lower-level data structure, and can be obtained using the pg_relation_filenode() function.

When a table or index exceeds 1 GB, it is divided into gigabyte-sized segments. The first segment’s file name is the same as the filenode; subsequent segments are named filenode.1, filenode.2,
Chapter 65. Database Physical Storage

etc. This arrangement avoids problems on platforms that have file size limitations. (Actually, 1 GB is just the default segment size. The segment size can be adjusted using the configuration option --with-segsize when building PostgreSQL.) In principle, free space map and visibility map forks could require multiple segments as well, though this is unlikely to happen in practice.

A table that has columns with potentially large entries will have an associated TOAST table, which is used for out-of-line storage of field values that are too large to keep in the table rows proper. pg_class.reltoastrelid links from a table to its TOAST table, if any. See Section 65.2 for more information.

The contents of tables and indexes are discussed further in Section 65.6.

Tablespaces make the scenario more complicated. Each user-defined tablespace has a symbolic link inside the PGDATA/pg_tblspc directory, which points to the physical tablespace directory (i.e., the location specified in the tablespace's CREATE TABLESPACE command). This symbolic link is named after the tablespace's OID. Inside the physical tablespace directory there is a subdirectory with a name that depends on the PostgreSQL server version, such as PG_9.0_201008051. (The reason for using this subdirectory is so that successive versions of the database can use the same CREATE TABLESPACE location value without conflicts.) Within the version-specific subdirectory, there is a subdirectory for each database that has elements in the tablespace, named after the database's OID. Tables and indexes are stored within that directory, using the filenode naming scheme. The pg_default tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/base. Similarly, the pg_global tablespace is not accessed through pg_tblspc, but corresponds to PGDATA/global.

The pg_relation_filepath() function shows the entire path (relative to PGDATA) of any relation. It is often useful as a substitute for remembering many of the above rules. But keep in mind that this function just gives the name of the first segment of the main fork of the relation — you may need to append a segment number and/or _fsm, _vm, or _init to find all the files associated with the relation.

Temporary files (for operations such as sorting more data than can fit in memory) are created within PGDATA/base/pgsql_tmp, or within a pgsql_tmp subdirectory of a tablespace directory if a tablescape other than pg_default is specified for them. The name of a temporary file has the form pgsql_tmpPPP.NNN, where PPP is the PID of the owning backend and NNN distinguishes different temporary files of that backend.

65.2. TOAST

This section provides an overview of TOAST (The Oversized-Attribute Storage Technique).

PostgreSQL uses a fixed page size (commonly 8 kB), and does not allow tuples to span multiple pages. Therefore, it is not possible to store very large field values directly. To overcome this limitation, large field values are compressed and/or broken up into multiple physical rows. This happens transparently to the user, with only small impact on most of the backend code. The technique is affectionately known as TOAST (or “the best thing since sliced bread”). The TOAST infrastructure is also used to improve handling of large data values in-memory.

Only certain data types support TOAST — there is no need to impose the overhead on data types that cannot produce large field values. To support TOAST, a data type must have a variable-length (varlena) representation, in which, ordinarily, the first four-byte word of any stored value contains the total length of the value in bytes (including itself). TOAST does not constrain the rest of the data type’s representation. The special representations collectively called TOASTed values work by modifying or reinterpreting this initial length word. Therefore, the C-level functions supporting a TOAST-able data type must be careful about how they handle potentially TOASTed input values: an input might not actually consist of a four-byte length word and contents until after it’s been detoasted.
TOAST usurps two bits of the varlena length word (the high-order bits on big-endian machines, the low-order bits on little-endian machines), thereby limiting the logical size of any value of a TOAST-able data type to 1 GB ($2^{30} - 1$ bytes). When both bits are zero, the value is an ordinary un-TOASTed value of the data type, and the remaining bits of the length word give the total datum size (including length word) in bytes. When the highest-order or lowest-order bit is set, the value has only a single-byte header instead of the normal four-byte header, and the remaining bits of that byte give the total datum size (including length byte) in bytes. This alternative supports space-efficient storage of values shorter than 127 bytes, while still allowing the data type to grow to 1 GB at need. Values with single-byte headers aren’t aligned on any particular boundary, whereas values with four-byte headers are aligned on at least a four-byte boundary; this omission of alignment padding provides additional space savings that is significant compared to short values. As a special case, if the remaining bits of a single-byte header are all zero (which would be impossible for a self-inclusive length), the value is a pointer to out-of-line data, with several possible alternatives as described below. The type and size of such a TOAST pointer are determined by a code stored in the second byte of the datum. Lastly, when the highest-order or lowest-order bit is clear but the adjacent bit is set, the content of the datum has been compressed and must be decompressed before use. In this case the remaining bits of the four-byte length word give the total size of the compressed datum, not the original data. Note that compression is also possible for out-of-line data but the varlena header does not tell whether it has occurred — the content of the TOAST pointer tells that, instead.

As mentioned, there are multiple types of TOAST pointer datums. The oldest and most common type is a pointer to out-of-line data stored in a TOAST table that is separate from, but associated with, the table containing the TOAST pointer datum itself. These on-disk pointer datums are created by the TOAST management code (in access/heap/tuptoaster.c) when a tuple to be stored on disk is too large to be stored as-is. Further details appear in Section 65.2.1. Alternatively, a TOAST pointer datum can contain a pointer to out-of-line data that appears elsewhere in memory. Such datums are necessarily short-lived, and will never appear on-disk, but they are very useful for avoiding copying and redundant processing of large data values. Further details appear in Section 65.2.2.

The compression technique used for either in-line or out-of-line compressed data is a fairly simple and very fast member of the LZ family of compression techniques. See src/common/pg_lzcompress.c for the details.

### 65.2.1. Out-of-line, on-disk TOAST storage

If any of the columns of a table are TOAST-able, the table will have an associated TOAST table, whose OID is stored in the table’s pg_class.reltoastrelid entry. On-disk TOASTed values are kept in the TOAST table, as described in more detail below.

Out-of-line values are divided (after compression if used) into chunks of at most TOAST_MAX CHUNK SIZE bytes (by default this value is chosen so that four chunk rows will fit on a page, making it about 2000 bytes). Each chunk is stored as a separate row in the TOAST table belonging to the owning table. Every TOAST table has the columns chunk_id (an OID identifying the particular TOASTed value), chunk_seq (a sequence number for the chunk within its value), and chunk_data (the actual data of the chunk). A unique index on chunk_id and chunk_seq provides fast retrieval of the values. A pointer datum representing an out-of-line on-disk TOASTed value therefore needs to store the OID of the TOAST table in which to look and the OID of the specific value (its chunk_id). For convenience, pointer datums also store the logical datum size (original uncompressed data length) and physical stored size (different if compression was applied). Allowing for the varlena header bytes, the total size of an on-disk TOAST pointer datum is therefore 18 bytes.
regardless of the actual size of the represented value.

The TOAST management code is triggered only when a row value to be stored in a table is wider than \texttt{TOAST\_TUPLE\_THRESHOLD} bytes (normally 2 kB). The TOAST code will compress and/or move field values out-of-line until the row value is shorter than \texttt{TOAST\_TUPLE\_TARGET} bytes (also normally 2 kB) or no more gains can be had. During an UPDATE operation, values of unchanged fields are normally preserved as-is; so an UPDATE of a row with out-of-line values incurs no TOAST costs if none of the out-of-line values change.

The TOAST management code recognizes four different strategies for storing TOAST-able columns on disk:

- **PLAIN** prevents either compression or out-of-line storage; furthermore it disables use of single-byte headers for varlena types. This is the only possible strategy for columns of non-TOAST-able data types.
- **EXTENDED** allows both compression and out-of-line storage. This is the default for most TOAST-able data types. Compression will be attempted first, then out-of-line storage if the row is still too big.
- **EXTERNAL** allows out-of-line storage but not compression. Use of \texttt{EXTERNAL} will make substring operations on wide text and bytea columns faster (at the penalty of increased storage space) because these operations are optimized to fetch only the required parts of the out-of-line value when it is not compressed.
- **MAIN** allows compression but not out-of-line storage. (Actually, out-of-line storage will still be performed for such columns, but only as a last resort when there is no other way to make the row small enough to fit on a page.)

Each TOAST-able data type specifies a default strategy for columns of that data type, but the strategy for a given table column can be altered with \texttt{ALTER TABLE SET STORAGE}.

This scheme has a number of advantages compared to a more straightforward approach such as allowing row values to span pages. Assuming that queries are usually qualified by comparisons against relatively small key values, most of the work of the executor will be done using the main row entry. The big values of TOASTed attributes will only be pulled out (if selected at all) at the time the result set is sent to the client. Thus, the main table is much smaller and more of its rows fit in the shared buffer cache than would be the case without any out-of-line storage. Sort sets shrink also, and sorts will more often be done entirely in memory. A little test showed that a table containing typical HTML pages and their URLs was stored in about half of the raw data size including the TOAST table, and that the main table contained only about 10% of the entire data (the URLs and some small HTML pages). There was no run time difference compared to an un-TOASTed comparison table, in which all the HTML pages were cut down to 7 kB to fit.

### 65.2.2. Out-of-line, in-memory TOAST storage

TOAST pointers can point to data that is not on disk, but is elsewhere in the memory of the current server process. Such pointers obviously cannot be long-lived, but they are nonetheless useful. There are currently two sub-cases: pointers to \texttt{indirect} data and pointers to \texttt{expanded} data.

Indirect TOAST pointers simply point at a non-indirect varlena value stored somewhere in memory. This case was originally created merely as a proof of concept, but it is currently used during logical decoding to avoid possibly having to create physical tuples exceeding 1 GB (as pulling all out-of-line field values into the tuple might do). The case is of limited use since the creator of the pointer datum.
Chapter 65. Database Physical Storage

is entirely responsible that the referenced data survives for as long as the pointer could exist, and there is no infrastructure to help with this.

Expanded TOAST pointers are useful for complex data types whose on-disk representation is not especially suited for computational purposes. As an example, the standard varlena representation of a PostgreSQL array includes dimensionality information, a nulls bitmap if there are any null elements, then the values of all the elements in order. When the element type itself is variable-length, the only way to find the $N$th element is to scan through all the preceding elements. This representation is appropriate for on-disk storage because of its compactness, but for computations with the array it’s much nicer to have an “expanded” or “deconstructed” representation in which all the element starting locations have been identified. The TOAST pointer mechanism supports this need by allowing a pass-by-reference Datum to point to either a standard varlena value (the on-disk representation) or a TOAST pointer that points to an expanded representation somewhere in memory. The details of this expanded representation are up to the data type, though it must have a standard header and meet the other API requirements given in src/include/utils/expandeddatum.h. C-level functions working with the data type can choose to handle either representation. Functions that do not know about the expanded representation, but simply apply PG_DETOAST_DATUM to their inputs, will automatically receive the traditional varlena representation; so support for an expanded representation can be introduced incrementally, one function at a time.

TOAST pointers to expanded values are further broken down into read-write and read-only pointers. The pointed-to representation is the same either way, but a function that receives a read-write pointer is allowed to modify the referenced value in-place, whereas one that receives a read-only pointer must not; it must first create a copy if it wants to modify the referenced value. This distinction and some associated conventions make it possible to avoid unnecessary copying of expanded values during query execution.

For all types of in-memory TOAST pointer, the TOAST management code ensures that no such pointer datum can accidentally get stored on disk. In-memory TOAST pointers are automatically expanded to normal in-line varlena values before storage — and then possibly converted to on-disk TOAST pointers, if the containing tuple would otherwise be too big.

65.3. Free Space Map

Each heap and index relation, except for hash indexes, has a Free Space Map (FSM) to keep track of available space in the relation. It’s stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a _fsm suffix. For example, if the filenode of a relation is 12345, the FSM is stored in a file called 12345_fsm, in the same directory as the main relation file.

The Free Space Map is organized as a tree of FSM pages. The bottom level FSM pages store the free space available on each heap (or index) page, using one byte to represent each such page. The upper levels aggregate information from the lower levels.

Within each FSM page is a binary tree, stored in an array with one byte per node. Each leaf node represents a heap page, or a lower level FSM page. In each non-leaf node, the higher of its children’s values is stored. The maximum value in the leaf nodes is therefore stored at the root.

See src/backend/storage/freespace/README for more details on how the FSM is structured, and how it’s updated and searched. The pg_freespacemap module can be used to examine the information stored in free space maps.
65.4. Visibility Map

Each heap relation has a Visibility Map (VM) to keep track of which pages contain only tuples that are known to be visible to all active transactions; it also keeps track of which pages contain only frozen tuples. It’s stored alongside the main relation data in a separate relation fork, named after the filenode number of the relation, plus a \_vm suffix. For example, if the filenode of a relation is 12345, the VM is stored in a file called 12345\_vm, in the same directory as the main relation file. Note that indexes do not have VMs.

The visibility map stores two bits per heap page. The first bit, if set, indicates that the page is all-visible, or in other words that the page does not contain any tuples that need to be vacuumed. This information can also be used by index-only scans to answer queries using only the index tuple. The second bit, if set, means that all tuples on the page have been frozen. That means that even an anti-wraparound vacuum need not revisit the page.

The map is conservative in the sense that we make sure that whenever a bit is set, we know the condition is true, but if a bit is not set, it might or might not be true. Visibility map bits are only set by vacuum, but are cleared by any data-modifying operations on a page.

The pg\_visibility module can be used to examine the information stored in the visibility map.

65.5. The Initialization Fork

Each unlogged table, and each index on an unlogged table, has an initialization fork. The initialization fork is an empty table or index of the appropriate type. When an unlogged table must be reset to empty due to a crash, the initialization fork is copied over the main fork, and any other forks are erased (they will be recreated automatically as needed).

65.6. Database Page Layout

This section provides an overview of the page format used within PostgreSQL tables and indexes. Sequences and TOAST tables are formatted just like a regular table.

In the following explanation, a byte is assumed to contain 8 bits. In addition, the term item refers to an individual data value that is stored on a page. In a table, an item is a row; in an index, an item is an index entry.

Every table and index is stored as an array of pages of a fixed size (usually 8 kB, although a different page size can be selected when compiling the server). In a table, all the pages are logically equivalent, so a particular item (row) can be stored in any page. In indexes, the first page is generally reserved as a metapage holding control information, and there can be different types of pages within the index, depending on the index access method.

Table 65-2 shows the overall layout of a page. There are five parts to each page.

Table 65-2. Overall Page Layout

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PageHeaderData</td>
<td>24 bytes long. Contains general information about the page, including free space pointers.</td>
</tr>
</tbody>
</table>

1. Actually, index access methods need not use this page format. All the existing index methods do use this basic format, but the data kept on index metapages usually doesn’t follow the item layout rules.
Chapter 65. Database Physical Storage

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ItemIdData</td>
<td>Array of (offset,length) pairs pointing to the actual items. 4 bytes per item.</td>
</tr>
<tr>
<td>Free space</td>
<td>The unallocated space. New item pointers are allocated from the start of this area, new items from the end.</td>
</tr>
<tr>
<td>Items</td>
<td>The actual items themselves.</td>
</tr>
<tr>
<td>Special space</td>
<td>Index access method specific data. Different methods store different data. Empty in ordinary tables.</td>
</tr>
</tbody>
</table>

The first 24 bytes of each page consists of a page header (PageHeaderData). Its format is detailed in Table 65-3. The first field tracks the most recent WAL entry related to this page. The second field contains the page checksum if data checksums are enabled. Next is a 2-byte field containing flag bits. This is followed by three 2-byte integer fields (pd_lower, pd_upper, and pd_special). These contain byte offsets from the page start to the start of unallocated space, to the end of unallocated space, and to the start of the special space. The next 2 bytes of the page header, pd_pagesize_version, store both the page size and a version indicator. Beginning with PostgreSQL 8.3 the version number is 4; PostgreSQL 8.1 and 8.2 used version number 3; PostgreSQL 8.0 used version number 2; PostgreSQL 7.3 and 7.4 used version number 1; prior releases used version number 0. (The basic page layout and header format has not changed in most of these versions, but the layout of heap row headers has.) The page size is basically only present as a cross-check; there is no support for having more than one page size in an installation. The last field is a hint that shows whether pruning the page is likely to be profitable: it tracks the oldest un-pruned XMAX on the page.

Table 65-3. PageHeaderData Layout

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pd_lsn</td>
<td>PageXLogRecPtr</td>
<td>8 bytes</td>
<td>LSN: next byte after last byte of xlog record for last change to this page</td>
</tr>
<tr>
<td>pd_checksum</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page checksum</td>
</tr>
<tr>
<td>pd_flags</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Flag bits</td>
</tr>
<tr>
<td>pd_lower</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of free space</td>
</tr>
<tr>
<td>pd_upper</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to end of free space</td>
</tr>
<tr>
<td>pd_special</td>
<td>LocationIndex</td>
<td>2 bytes</td>
<td>Offset to start of special space</td>
</tr>
<tr>
<td>pd_pagesize_version</td>
<td>uint16</td>
<td>2 bytes</td>
<td>Page size and layout version number information</td>
</tr>
<tr>
<td>pd_prune_xid</td>
<td>TransactionId</td>
<td>4 bytes</td>
<td>Oldest unpruned XMAX on page, or zero if none</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/storage/bufpage.h.

Following the page header are item identifiers (ItemIdData), each requiring four bytes. An item
Chapter 65. Database Physical Storage

Identifier contains a byte-offset to the start of an item, its length in bytes, and a few attribute bits which affect its interpretation. New item identifiers are allocated as needed from the beginning of the unallocated space. The number of item identifiers present can be determined by looking at pd_lower, which is increased to allocate a new identifier. Because an item identifier is never moved until it is freed, its index can be used on a long-term basis to reference an item, even when the item itself is moved around on the page to compact free space. In fact, every pointer to an item (ItemPointer, also known as CTID) created by PostgreSQL consists of a page number and the index of an item identifier.

The items themselves are stored in space allocated backwards from the end of unallocated space. The exact structure varies depending on what the table is to contain. Tables and sequences both use a structure named HeapTupleHeaderData, described below.

The final section is the “special section” which can contain anything the access method wishes to store. For example, b-tree indexes store links to the page’s left and right siblings, as well as some other data relevant to the index structure. Ordinary tables do not use a special section at all (indicated by setting pd_special to equal the page size).

All table rows are structured in the same way. There is a fixed-size header (occupying 23 bytes on most machines), followed by an optional null bitmap, an optional object ID field, and the user data. The header is detailed in Table 65-4. The actual user data (columns of the row) begins at the offset indicated by t_hoff, which must always be a multiple of the MAXALIGN distance for the platform.

The null bitmap is only present if the HEAP_HASNULL bit is set in t_infomask. If it is present it begins just after the fixed header and occupies enough bytes to have one bit per data column (that is, t_natts bits altogether). In this list of bits, a 1 bit indicates not-null, a 0 bit is a null. When the bitmap is not present, all columns are assumed not-null. The object ID is only present if the HEAP_HASOID bit is set in t_infomask. If present, it appears just before the t_hoff boundary. Any padding needed to make t_hoff a MAXALIGN multiple will appear between the null bitmap and the object ID. (This in turn ensures that the object ID is suitably aligned.)

Table 65-4. HeapTupleHeaderData Layout

<table>
<thead>

</tr>
<tr>
<td>t_hoff</td>
<td>uint8</td>
<td>1 byte</td>
<td>offset to user data</td>
</tr>
</tbody>
</table>

All the details can be found in src/include/access/htup_details.h.

Interpreting the actual data can only be done with information obtained from other tables, mostly pg_attribute. The key values needed to identify field locations are attlen and attalign. There is no way to directly get a particular attribute, except when there are only fixed width fields and no null
values. All this trickery is wrapped up in the functions heap_getattr, fastgetattr and heap_getsysattr.

To read the data you need to examine each attribute in turn. First check whether the field is NULL according to the null bitmap. If it is, go to the next. Then make sure you have the right alignment. If the field is a fixed width field, then all the bytes are simply placed. If it’s a variable length field (attlen = -1) then it’s a bit more complicated. All variable-length data types share the common header structure struct varlena, which includes the total length of the stored value and some flag bits. Depending on the flags, the data can be either inline or in a TOAST table; it might be compressed, too (see Section 65.2).
Chapter 66. BKI Backend Interface

Backend Interface (BKI) files are scripts in a special language that is understood by the PostgreSQL backend when running in the “bootstrap” mode. The bootstrap mode allows system catalogs to be created and filled from scratch, whereas ordinary SQL commands require the catalogs to exist already. BKI files can therefore be used to create the database system in the first place. (And they are probably not useful for anything else.)

initdb uses a BKI file to do part of its job when creating a new database cluster. The input file used by initdb is created as part of building and installing PostgreSQL by a program named genbki.pl, which reads some specially formatted C header files in the src/include/catalog/ directory of the source tree. The created BKI file is called postgres.bki and is normally installed in the share subdirectory of the installation tree.

Related information can be found in the documentation for initdb.

66.1. BKI File Format

This section describes how the PostgreSQL backend interprets BKI files. This description will be easier to understand if the postgres.bki file is at hand as an example.

BKI input consists of a sequence of commands. Commands are made up of a number of tokens, depending on the syntax of the command. Tokens are usually separated by whitespace, but need not be if there is no ambiguity. There is no special command separator; the next token that syntactically cannot belong to the preceding command starts a new one. (Usually you would put a new command on a new line, for clarity.) Tokens can be certain key words, special characters (parentheses, commas, etc.), numbers, or double-quoted strings. Everything is case sensitive.

Lines starting with # are ignored.

66.2. BKI Commands

```
create tablename tableoid [bootstrap] [shared_relation] [without_oids]
[rowtype_oid oid] (name1 = type1 [FORCE NOT NULL | FORCE NULL ] [, name2 = type2
[FORCE NOT NULL | FORCE NULL ], ...])
```

Create a table named `tablename`, and having the OID `tableoid`, with the columns given in parentheses.

The following column types are supported directly by `bootstrap.c`: bool, bytea, char (1 byte), name, int2, int4, regproc, regclass, regtype, text, oid, tid, xid, cid, int2vector, oidvector, _int4 (array), _text (array), _oid (array), _char (array), _aclitem (array). Although it is possible to create tables containing columns of other types, this cannot be done until after `pg_type` has been created and filled with appropriate entries. (That effectively means that only these column types can be used in bootstrapped tables, but non-bootstrap catalogs can contain any built-in type.)

When `bootstrap` is specified, the table will only be created on disk; nothing is entered into `pg_class`, `pg_attribute`, etc. for it. Thus the table will not be accessible by ordinary SQL
operations until such entries are made the hard way (with `insert` commands). This option is used for creating `pg_class` etc themselves.

The table is created as shared if `shared_relation` is specified. It will have OIDs unless `without_oids` is specified. The table’s row type OID (pg_type OID) can optionally be specified via the `rowtype_oid` clause; if not specified, an OID is automatically generated for it. (The `rowtype_oid` clause is useless if `bootstrap` is specified, but it can be provided anyway for documentation.)

```
open tablename
```

Open the table named `tablename` for insertion of data. Any currently open table is closed.

```
close [tablename]
```

Close the open table. The name of the table can be given as a cross-check, but this is not required.

```
insert [OID = oid_value] ( value1 value2 ...)
```

Insert a new row into the open table using `value1`, `value2`, etc., for its column values and `oid_value` for its OID. If `oid_value` is zero (0) or the clause is omitted, and the table has OIDs, then the next available OID is assigned.

NULL values can be specified using the special key word `_null_`. Values containing spaces must be double quoted.

```
declare [unique] index indexname indexoid on tablename using amname ( opclass1 name1 [, ...] )
```

Create an index named `indexname`, having OID `indexoid`, on the table named `tablename`, using the `amname` access method. The fields to index are called `name1`, `name2` etc., and the operator classes to use are `opclass1`, `opclass2` etc., respectively. The index file is created and appropriate catalog entries are made for it, but the index contents are not initialized by this command.

```
declare toast toasttableoid toastindexoid on tablename
```

Create a TOAST table for the table named `tablename`. The TOAST table is assigned OID `toasttableoid` and its index is assigned OID `toastindexoid`. As with `declare index`, filling of the index is postponed.

```
build indices
```

Fill in the indices that have previously been declared.

### 66.3. Structure of the Bootstrap BKI File

The `open` command cannot be used until the tables it uses exist and have entries for the table that is to be opened. (These minimum tables are `pg_class`, `pg_attribute`, `pg_proc`, and `pg_type`.) To allow those tables themselves to be filled, `create` with the `bootstrap` option implicitly opens the created table for data insertion.

Also, the `declare index` and `declare toast` commands cannot be used until the system catalogs they need have been created and filled in.

Thus, the structure of the `postgres.bki` file has to be:

1. `create bootstrap` one of the critical tables
2. `insert` data describing at least the critical tables
3. close
4. Repeat for the other critical tables.
5. create (without bootstrap) a noncritical table
6. open
7. insert desired data
8. close
9. Repeat for the other noncritical tables.
10. Define indexes and toast tables.
11. build indices

There are doubtless other, undocumented ordering dependencies.

### 66.4. Example

The following sequence of commands will create the table test_table with OID 420, having two columns cola and colb of type int4 and text, respectively, and insert two rows into the table:

```sql
create test_table 420 (cola = int4, colb = text)
open test_table
insert OID=421 ( 1 "value1" )
insert OID=422 ( 2 _null_ )
close test_table
```
Chapter 67. How the Planner Uses Statistics

This chapter builds on the material covered in Section 14.1 and Section 14.2 to show some additional details about how the planner uses the system statistics to estimate the number of rows each part of a query might return. This is a significant part of the planning process, providing much of the raw material for cost calculation.

The intent of this chapter is not to document the code in detail, but to present an overview of how it works. This will perhaps ease the learning curve for someone who subsequently wishes to read the code.

67.1. Row Estimation Examples

The examples shown below use tables in the PostgreSQL regression test database. The outputs shown are taken from version 8.3. The behavior of earlier (or later) versions might vary. Note also that since `ANALYZE` uses random sampling while producing statistics, the results will change slightly after any new `ANALYZE`.

Let's start with a very simple query:

```sql
EXPLAIN SELECT * FROM tenk1;
```

```
QUERY PLAN
-------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..458.00 rows=10000 width=244)
```

How the planner determines the cardinality of `tenk1` is covered in Section 14.2, but is repeated here for completeness. The number of pages and rows is looked up in `pg_class`:

```sql
SELECT relpages, reltuples FROM pg_class WHERE relname = 'tenk1';
```

```
relpages | reltuples
----------+-----------
358 | 10000
```

These numbers are current as of the last `VACUUM` or `ANALYZE` on the table. The planner then fetches the actual current number of pages in the table (this is a cheap operation, not requiring a table scan). If that is different from `relpages` then `reltuples` is scaled accordingly to arrive at a current number-of-rows estimate. In the example above, the value of `relpages` is up-to-date so the rows estimate is the same as `reltuples`.

Let's move on to an example with a range condition in its `WHERE` clause:

```sql
EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000;
```

```
QUERY PLAN
--------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=24.06..394.64 rows=1007 width=244)
  Recheck Cond: (unique1 < 1000)
--> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
    Index Cond: (unique1 < 1000)
```
Chapter 67. How the Planner Uses Statistics

The planner examines the WHERE clause condition and looks up the selectivity function for the operator < in pg_operator. This is held in the column oprrest, and the entry in this case is scalarltssel. The scalarltssel function retrieves the histogram for uniquel from pg_statistics. For manual queries it is more convenient to look in the simpler pg_stats view:

```
SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='uniquel';
```

```
histogram_bounds
-----------------------------
(0,993,1997,3050,4040,5036,5957,7057,8029,9016,9995)
```

Next the fraction of the histogram occupied by “< 1000” is worked out. This is the selectivity. The histogram divides the range into equal frequency buckets, so all we have to do is locate the bucket that our value is in and count part of it and all of the ones before. The value 1000 is clearly in the second bucket (993-1997). Assuming a linear distribution of values inside each bucket, we can calculate the selectivity as:

\[
\text{selectivity} = \frac{1 + \frac{1000 - \text{bucket}[2].\text{min}}{\text{bucket}[2].\text{max} - \text{bucket}[2].\text{min}}}{} / \text{num_buckets}
\]

\[
= \frac{1 + \frac{1000 - 993}{1997 - 993}}{10}
\]

\[
= 0.100697
\]

that is, one whole bucket plus a linear fraction of the second, divided by the number of buckets. The estimated number of rows can now be calculated as the product of the selectivity and the cardinality of tenk1:

\[
\text{rows} = \text{rel_cardinality} \times \text{selectivity}
\]

\[
= 10000 \times 0.100697
\]

\[
= 1007 \text{ (rounding off)}
\]

Next let’s consider an example with an equality condition in its WHERE clause:

```
EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'CRAAAA';
```

```
QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1  (cost=0.00..483.00 rows=30 width=244)
  Filter: (stringu1 = 'CRAAAA'::name)
```

Again the planner examines the WHERE clause condition and looks up the selectivity function for =, which is eqsel. For equality estimation the histogram is not useful; instead the list of most common values (MCVs) is used to determine the selectivity. Let’s have a look at the MCVs, with some additional columns that will be useful later:

```
SELECT null_frac, n_distinct, most_common_vals, most_common_freqs FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';
```

```
null_frac | 0
n_distinct | 676

m最多_common_freqs | {0.00333333, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003, 0.003}
```

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):

Since CRAAAA appears in the list of MCVs, the selectivity is merely the corresponding entry in the list of most common frequencies (MCFs):
Chapter 67. How the Planner Uses Statistics

selectivity = mcf[3]  
  = 0.003

As before, the estimated number of rows is just the product of this with the cardinality of tenk1:

rows = 10000 * 0.003  
  = 30

Now consider the same query, but with a constant that is not in the MCV list:

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 = 'xxx';

QUERY PLAN
----------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=15 width=244)  
  Filter: (stringu1 = 'xxx '::name)

This is quite a different problem: how to estimate the selectivity when the value is not in the MCV list. The approach is to use the fact that the value is not in the list, combined with the knowledge of the frequencies for all of the MCVs:

\[
\text{selectivity} = \frac{1 - \sum (\text{mfv})}{\text{num\_distinct} - \text{num\_mcv}} = \frac{1 - (0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003)}{(676 - 10)}
\]

\[
= 0.0014559
\]

That is, add up all the frequencies for the MCVs and subtract them from one, then divide by the number of other distinct values. This amounts to assuming that the fraction of the column that is not any of the MCVs is evenly distributed among all the other distinct values. Notice that there are no null values so we don’t have to worry about those (otherwise we’d subtract the null fraction from the numerator as well). The estimated number of rows is then calculated as usual:

rows = 10000 * 0.0014559  
  = 15 (rounding off)

The previous example with unique1 < 1000 was an oversimplification of what scalarltsel really does; now that we have seen an example of the use of MCVs, we can fill in some more detail. The example was correct as far as it went, because since unique1 is a unique column it has no MCVs (obviously, no value is any more common than any other value). For a non-unique column, there will normally be both a histogram and an MCV list, and the histogram does not include the portion of the column population represented by the MCVs. We do things this way because it allows more precise estimation. In this situation scalarltsel directly applies the condition (e.g., “< 1000”) to each value of the MCV list, and adds up the frequencies of the MCVs for which the condition is true. This gives an exact estimate of the selectivity within the portion of the table that is MCVs. The histogram is then used in the same way as above to estimate the selectivity in the portion of the table that is not MCVs, and then the two numbers are combined to estimate the overall selectivity. For example, consider

EXPLAIN SELECT * FROM tenk1 WHERE stringu1 < 'IAAAAA';

QUERY PLAN
------------------------------------------------------------
Seq Scan on tenk1 (cost=0.00..483.00 rows=3077 width=244)
Chapter 67. How the Planner Uses Statistics

Filter: (stringu1 < 'IAAAAA':::name)

We already saw the MCV information for stringu1, and here is its histogram:

SELECT histogram_bounds FROM pg_stats
WHERE tablename='tenk1' AND attname='stringu1';

histogram_bounds
--------------------------------------------------------------------------------
(AAAAAA, CQAAAA, FRAAAA, IBAAAA, KRAAAA, NFAAAA, PSAAAA, SGAAAA, VAAAAA, XLAAAA, ZZAAAA)

Checking the MCV list, we find that the condition stringu1 < 'IAAAAA' is satisfied by the first six entries and not the last four, so the selectivity within the MCV part of the population is

selectivity = sum(relevant mvfs)
= 0.00333333 + 0.003 + 0.003 + 0.003 + 0.003 + 0.003
= 0.01833333

Summing all the MCFs also tells us that the total fraction of the population represented by MCVs is 0.03033333, and therefore the fraction represented by the histogram is 0.96966667 (again, there are no nulls, else we’d have to exclude them here). We can see that the value IAAAAA falls nearly at the end of the third histogram bucket. Using some rather cheesy assumptions about the frequency of different characters, the planner arrives at the estimate 0.298387 for the portion of the histogram population that is less than IAAAAA. We then combine the estimates for the MCV and non-MCV populations:

selectivity = mcv_selectivity + histogram_selectivity * histogram_fraction
= 0.01833333 + 0.298387 * 0.96966667
= 0.307669

rows = 10000 * 0.307669
= 3077 (rounding off)

In this particular example, the correction from the MCV list is fairly small, because the column distribution is actually quite flat (the statistics showing these particular values as being more common than others are mostly due to sampling error). In a more typical case where some values are significantly more common than others, this complicated process gives a useful improvement in accuracy because the selectivity for the most common values is found exactly.

Now let’s consider a case with more than one condition in the WHERE clause:

EXPLAIN SELECT * FROM tenk1 WHERE unique1 < 1000 AND stringu1 = 'xxx';

QUERY PLAN
--------------------------------------------------------------------------------
Bitmap Heap Scan on tenk1 (cost=23.80..396.91 rows=1 width=244)
  Recheck Cond: (unique1 < 1000)
  Filter: (stringu1 = 'xxx':::name)
    -> Bitmap Index Scan on tenk1_unique1 (cost=0.00..23.80 rows=1007 width=0)
      Index Cond: (unique1 < 1000)

The planner assumes that the two conditions are independent, so that the individual selectivities of the clauses can be multiplied together:

selectivity = selectivity(unique1 < 1000) * selectivity(stringu1 = 'xxx')
= 0.100697 * 0.0014559
= 0.0001466
Chapter 67. How the Planner Uses Statistics

rows = 10000 * 0.0001466
= 1 (rounding off)

Notice that the number of rows estimated to be returned from the bitmap index scan reflects only the condition used with the index; this is important since it affects the cost estimate for the subsequent heap fetches.

Finally we will examine a query that involves a join:

EXPLAIN SELECT * FROM tenk1 t1, tenk2 t2
WHERE t1.unique1 < 50 AND t1.unique2 = t2.unique2;

QUERY PLAN

<table>
<thead>
<tr>
<th>Nested Loop (cost=4.64..456.23 rows=50 width=488)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-&gt; Bitmap Heap Scan on tenk1 t1 (cost=4.64..142.17 rows=50 width=244)</td>
</tr>
<tr>
<td>Recheck Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Bitmap Index Scan on tenk1_unique1 (cost=0.00..4.63 rows=50 width=0)</td>
</tr>
<tr>
<td>Index Cond: (unique1 &lt; 50)</td>
</tr>
<tr>
<td>-&gt; Index Scan using tenk2_unique2 on tenk2 t2 (cost=0.00..6.27 rows=1 width=244)</td>
</tr>
<tr>
<td>Index Cond: (unique2 = t1.unique2)</td>
</tr>
</tbody>
</table>

The restriction on tenk1, unique1 < 50, is evaluated before the nested-loop join. This is handled analogously to the previous range example. This time the value 50 falls into the first bucket of the unique1 histogram:

\[
\text{selectivity} = \frac{(0 + (50 - \text{bucket}[1].\text{min})/(\text{bucket}[1].\text{max} - \text{bucket}[1].\text{min}))}{\text{num_buckets}} \\
= \frac{(0 + (50 - 0)/(993 - 0))}{10} \\
= 0.005035
\]

rows = 10000 * 0.005035
= 50 (rounding off)

The restriction for the join is t2.unique2 = t1.unique2. The operator is just our familiar =, however the selectivity function is obtained from the oprjoin column of pg_operator, and is eqjoinsel. eqjoinsel looks up the statistical information for both tenk2 and tenk1:

```sql
SELECT tablename, null_frac, n_distinct, most_common_vals FROM pg_stats WHERE tablename IN ('tenk1', 'tenk2') AND attname='unique2';
```

<table>
<thead>
<tr>
<th>tablename</th>
<th>null_frac</th>
<th>n_distinct</th>
<th>most_common_vals</th>
</tr>
</thead>
<tbody>
<tr>
<td>tenk1</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
<tr>
<td>tenk2</td>
<td>0</td>
<td>-1</td>
<td></td>
</tr>
</tbody>
</table>

In this case there is no MCV information for unique2 because all the values appear to be unique, so we use an algorithm that relies only on the number of distinct values for both relations together with their null fractions:

\[
\text{selectivity} = (1 - \text{nullfrac1}) \times (1 - \text{nullfrac2}) \times \min(1/\text{num.distinct1}, 1/\text{num.distinct2}) \\
= (1 - 0) \times (1 - 0) / \max(10000, 10000) \\
= 0.0001
\]

This is, subtract the null fraction from one for each of the relations, and divide by the maximum of the numbers of distinct values. The number of rows that the join is likely to emit is calculated as the cardinality of the Cartesian product of the two inputs, multiplied by the selectivity:
Chapter 67. How the Planner Uses Statistics

rows = (outer_cardinality * inner_cardinality) * selectivity
  = (50 * 10000) * 0.0001
  = 50

Had there been MCV lists for the two columns, eqjoinsel would have used direct comparison of the MCV lists to determine the join selectivity within the part of the column populations represented by the MCVs. The estimate for the remainder of the populations follows the same approach shown here.

Notice that we showed inner_cardinality as 10000, that is, the unmodified size of tenk2. It might appear from inspection of the EXPLAIN output that the estimate of join rows comes from 50 * 1, that is, the number of outer rows times the estimated number of rows obtained by each inner index scan on tenk2. But this is not the case: the join relation size is estimated before any particular join plan has been considered. If everything is working well then the two ways of estimating the join size will produce about the same answer, but due to round-off error and other factors they sometimes diverge significantly.

For those interested in further details, estimation of the size of a table (before any WHERE clauses) is done in src/backend/optimizer/util/plancat.c. The generic logic for clause selectivities is in src/backend/optimizer/path/clausesel.c. The operator-specific selectivity functions are mostly found in src/backend/utils/adt/selfuncs.c.

67.2. Planner Statistics and Security

Access to the table pg_statistic is restricted to superusers, so that ordinary users cannot learn about the contents of the tables of other users from it. Some selectivity estimation functions will use a user-provided operator (either the operator appearing in the query or a related operator) to analyze the stored statistics. For example, in order to determine whether a stored most common value is applicable, the selectivity estimator will have to run the appropriate = operator to compare the constant in the query to the stored value. Thus the data in pg_statistic is potentially passed to user-defined operators. An appropriately crafted operator can intentionally leak the passed operands (for example, by logging them or writing them to a different table), or accidentally leak them by showing their values in error messages, in either case possibly exposing data from pg_statistic to a user who should not be able to see it.

In order to prevent this, the following applies to all built-in selectivity estimation functions. When planning a query, in order to be able to use stored statistics, the current user must either have SELECT privilege on the table or the involved columns, or the operator used must be LEAKPROOF (more accurately, the function that the operator is based on). If not, then the selectivity estimator will behave as if no statistics are available, and the planner will proceed with default or fall-back assumptions.

If a user does not have the required privilege on the table or columns, then in many cases the query will ultimately receive a permission-denied error, in which case this mechanism is invisible in practice. But if the user is reading from a security-barrier view, then the planner might wish to check the statistics of an underlying table that is otherwise inaccessible to the user. In that case, the operator should be leak-proof or the statistics will not be used. There is no direct feedback about that, except that the plan might be suboptimal. If one suspects that this is the case, one could try running the query as a more privileged user, to see if a different plan results.

This restriction applies only to cases where the planner would need to execute a user-defined operator on one or more values from pg_statistic. Thus the planner is permitted to use generic statistical
information, such as the fraction of null values or the number of distinct values in a column, regardless of access privileges.

Selectivity estimation functions contained in third-party extensions that potentially operate on statistics with user-defined operators should follow the same security rules. Consult the PostgreSQL source code for guidance.
VIII. Appendixes
Appendix A. PostgreSQL Error Codes

All messages emitted by the PostgreSQL server are assigned five-character error codes that follow the SQL standard’s conventions for “SQLSTATE” codes. Applications that need to know which error condition has occurred should usually test the error code, rather than looking at the textual error message. The error codes are less likely to change across PostgreSQL releases, and also are not subject to change due to localization of error messages. Note that some, but not all, of the error codes produced by PostgreSQL are defined by the SQL standard; some additional error codes for conditions not defined by the standard have been invented or borrowed from other databases.

According to the standard, the first two characters of an error code denote a class of errors, while the last three characters indicate a specific condition within that class. Thus, an application that does not recognize the specific error code might still be able to infer what to do from the error class.

Table A-1 lists all the error codes defined in PostgreSQL 9.6.13. (Some are not actually used at present, but are defined by the SQL standard.) The error classes are also shown. For each error class there is a “standard” error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The symbol shown in the column “Condition Name” is the condition name to use in PL/pgSQL. Condition names can be written in either upper or lower case. (Note that PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.)

For some types of errors, the server reports the name of a database object (a table, table column, data type, or constraint) associated with the error; for example, the name of the unique constraint that caused a unique_violation error. Such names are supplied in separate fields of the error report message so that applications need not try to extract them from the possibly-localized human-readable text of the message. As of PostgreSQL 9.3, complete coverage for this feature exists only for errors in SQLSTATE class 23 (integrity constraint violation), but this is likely to be expanded in future.

Appendix B. Date/Time Support

PostgreSQL uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information can be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

This appendix includes information on the content of these lookup tables and describes the steps used by the parser to decode dates and times.

B.1. Date/Time Input Interpretation

Date/time input strings are decoded using the following procedure.

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
   a. If the numeric token contains a colon (:) this is a time string. Include all subsequent digits and colons.
   b. If the numeric token contains a dash (-), slash (/), or two or more dots (.), this is a date string which might have a text month. If a date token has already been seen, it is instead interpreted as a time zone name (e.g., America/New_York).
   c. If the token is numeric only, then it is either a single field or an ISO 8601 concatenated date (e.g., 19990113 for January 13, 1999) or time (e.g., 141516 for 14:15:16).
   d. If the token starts with a plus (+) or minus (-), then it is either a numeric time zone or a special field.

2. If the token is an alphabetic string, match up with possible strings:
   a. See if the token matches any known time zone abbreviation. These abbreviations are supplied by the configuration file described in Section B.4.
   b. If not found, search an internal table to match the token as either a special string (e.g., today), day (e.g., Thursday), month (e.g., January), or noise word (e.g., at, on).
   c. If still not found, throw an error.

3. When the token is a number or number field:
   a. If there are eight or six digits, and if no other date fields have been previously read, then interpret as a “concatenated date” (e.g., 19990118 or 990118). The interpretation is YYYYMMDD or YMMDD.
   b. If the token is three digits and a year has already been read, then interpret as day of year.
   c. If four or six digits and a year has already been read, then interpret as a time (HHMM or HHMMSS).
d. If three or more digits and no date fields have yet been found, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
e. Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.

4. If BC has been specified, negate the year and add one for internal storage. (There is no year zero in the Gregorian calendar, so numerically 1 BC becomes year zero.)

5. If BC was not specified, and if the year field was two digits in length, then adjust the year to four digits. If the field is less than 70, then add 2000, otherwise add 1900.

Tip: Gregorian years AD 1-99 can be entered by using 4 digits with leading zeros (e.g., 0099 is AD 99).

B.2. Handling of Invalid or Ambiguous Timestamps

Ordinarily, if a date/time string is syntactically valid but contains out-of-range field values, an error will be thrown. For example, input specifying the 31st of February will be rejected.

During a daylight-savings-time transition, it is possible for a seemingly valid timestamp string to represent a nonexistent or ambiguous timestamp. Such cases are not rejected; the ambiguity is resolved by determining which UTC offset to apply. For example, supposing that the TimeZone parameter is set to America/New_York, consider

```
=> SELECT '2018-03-11 02:30'::timestamptz;
timestamptz
------------------------
2018-03-11 03:30:00-04
(1 row)
```

Because that day was a spring-forward transition date in that time zone, there was no civil time instant 2:30AM; clocks jumped forward from 2AM EST to 3AM EDT. PostgreSQL interprets the given time as if it were standard time (UTC-5), which then renders as 3:30AM EDT (UTC-4).

Conversely, consider the behavior during a fall-back transition:

```
=> SELECT '2018-11-04 02:30'::timestamptz;
timestamptz
------------------------
2018-11-04 02:30:00-05
(1 row)
```

On that date, there were two possible interpretations of 2:30AM; there was 2:30AM EDT, and then an hour later after the reversion to standard time, there was 2:30AM EST. Again, PostgreSQL interprets the given time as if it were standard time (UTC-5). We can force the matter by specifying daylight-savings time:

```
=> SELECT '2018-11-04 02:30 EDT'::timestamptz;
timestamptz
------------------------
```

2208
Appendix B. Date/Time Support

This timestamp could validly be rendered as either 2:30 UTC-4 or 1:30 UTC-5; the timestamp output code chooses the latter.

The precise rule that is applied in such cases is that an invalid timestamp that appears to fall within a jump-forward daylight savings transition is assigned the UTC offset that prevailed in the time zone just before the transition, while an ambiguous timestamp that could fall on either side of a jump-back transition is assigned the UTC offset that prevailed just after the transition. In most time zones this is equivalent to saying that “the standard-time interpretation is preferred when in doubt”.

In all cases, the UTC offset associated with a timestamp can be specified explicitly, using either a numeric UTC offset or a time zone abbreviation that corresponds to a fixed UTC offset. The rule just given applies only when it is necessary to infer a UTC offset for a time zone in which the offset varies.

B.3. Date/Time Key Words

Table B-1 shows the tokens that are recognized as names of months.

Table B-1. Month Names

<table>
<thead>
<tr>
<th>Month</th>
<th>Abbreviations</th>

<tr>
<td>T</td>
<td>Next field is time</td>
</tr>
</tbody>
</table>

B.4. Date/Time Configuration Files

Since timezone abbreviations are not well standardized, PostgreSQL provides a means to customize the set of abbreviations accepted by the server. The timezone_abbreviations run-time parameter determines the active set of abbreviations. While this parameter can be altered by any database user, the possible values for it are under the control of the database administrator — they are in fact names of configuration files stored in .../share/timezonesets/ of the installation directory. By adding or altering files in that directory, the administrator can set local policy for timezone abbreviations.

timezone_abbreviations can be set to any file name found in .../share/timezonesets/, if the file’s name is entirely alphabetic. (The prohibition against non-alphabetic characters in timezone_abbreviations prevents reading files outside the intended directory, as well as reading editor backup files and other extraneous files.)

A timezone abbreviation file can contain blank lines and comments beginning with #. Non-comment lines must have one of these formats:

zone_abbreviation offset
zone_abbreviation offset D
zone_abbreviation time_zone_name
@INCLUDE file_name
@OVERRIDE

A zone_abbreviation is just the abbreviation being defined. An offset is an integer giving the equivalent offset in seconds from UTC, positive being east from Greenwich and negative being west. For example, -18000 would be five hours west of Greenwich, or North American east coast standard time. D indicates that the zone name represents local daylight-savings time rather than standard time.

Alternatively, a time_zone_name can be given, referencing a zone name defined in the IANA timezone database. The zone’s definition is consulted to see whether the abbreviation is or has been in use in that zone, and if so, the appropriate meaning is used — that is, the meaning that was currently in use at the timestamp whose value is being determined, or the meaning in use immediately before that if it wasn’t current at that time, or the oldest meaning if it was used only after that time. This behavior is essential for dealing with abbreviations whose meaning has historically varied. It is also allowed to define an abbreviation in terms of a zone name in which that abbreviation does not appear; then using the abbreviation is just equivalent to writing out the zone name.
Appendix B. Date/Time Support

Tip: Using a simple integer offset is preferred when defining an abbreviation whose offset from UTC has never changed, as such abbreviations are much cheaper to process than those that require consulting a time zone definition.

The @INCLUDE syntax allows inclusion of another file in the .../share/timezonesets/ directory. Inclusion can be nested, to a limited depth.

The @OVERRIDE syntax indicates that subsequent entries in the file can override previous entries (typically, entries obtained from included files). Without this, conflicting definitions of the same timezone abbreviation are considered an error.

In an unmodified installation, the file Default contains all the non-conflicting time zone abbreviations for most of the world. Additional files Australia and India are provided for those regions: these files first include the Default file and then add or modify abbreviations as needed.

For reference purposes, a standard installation also contains files Africa.txt, America.txt, etc, containing information about every time zone abbreviation known to be in use according to the IANA timezone database. The zone name definitions found in these files can be copied and pasted into a custom configuration file as needed. Note that these files cannot be directly referenced as timezone_abbreviations settings, because of the dot embedded in their names.

Note: If an error occurs while reading the time zone abbreviation set, no new value is applied and the old set is kept. If the error occurs while starting the database, startup fails.

Caution

Time zone abbreviations defined in the configuration file override non-timezone meanings built into PostgreSQL. For example, the Australia configuration file defines SAT (for South Australian Standard Time). When this file is active, SAT will not be recognized as an abbreviation for Saturday.

Caution

If you modify files in .../share/timezonesets/, it is up to you to make backups — a normal database dump will not include this directory.

B.5. History of Units

The SQL standard states that “Within the definition of a ‘datetime literal’, the ‘datetime values’ are constrained by the natural rules for dates and times according to the Gregorian calendar”. PostgreSQL follows the SQL standard’s lead by counting dates exclusively in the Gregorian calendar, even for years before that calendar was in use. This rule is known as the proleptic Gregorian calendar.

The Julian calendar was introduced by Julius Caesar in 45 BC. It was in common use in the Western world until the year 1582, when countries started changing to the Gregorian calendar. In the Julian calendar, the tropical year is approximated as 365 1/4 days = 365.25 days. This gives an error of about 1 day in 128 years.

The accumulating calendar error prompted Pope Gregory XIII to reform the calendar in accordance with instructions from the Council of Trent. In the Gregorian calendar, the tropical year is approxi-
mated as 365 + 97 / 400 days = 365.2425 days. Thus it takes approximately 3300 years for the tropical
to shift one day with respect to the Gregorian calendar.

The approximation 365+97/400 is achieved by having 97 leap years every 400 years, using the fol-
lowing rules:

Every year divisible by 4 is a leap year.
However, every year divisible by 100 is not a leap year.
However, every year divisible by 400 is a leap year after all.

So, 1700, 1800, 1900, 2100, and 2200 are not leap years. But 1600, 2000, and 2400 are leap years.
By contrast, in the older Julian calendar all years divisible by 4 are leap years.

The papal bull of February 1582 decreed that 10 days should be dropped from October 1582 so that
15 October should follow immediately after 4 October. This was observed in Italy, Poland, Portugal,
and Spain. Other Catholic countries followed shortly after, but Protestant countries were reluctant to
change, and the Greek Orthodox countries didn’t change until the start of the 20th century. The reform
was observed by Great Britain and its dominions (including what is now the USA) in 1752. Thus 2
September 1752 was followed by 14 September 1752. This is why Unix systems that have the cal
program produce the following:

```
$ cal 9 1752
  September 1752
 Su Mo Tu We Th Fr Sa
  1  2  14  15  16
 17 18 19 20 21 22 23
 24 25 26 27 28 29 30
```

But, of course, this calendar is only valid for Great Britain and dominions, not other places. Since it
would be difficult and confusing to try to track the actual calendars that were in use in various places
at various times, PostgreSQL does not try, but rather follows the Gregorian calendar rules for all dates,
even though this method is not historically accurate.

Different calendars have been developed in various parts of the world, many predating the Gregorian
system. For example, the beginnings of the Chinese calendar can be traced back to the 14th cen-
tury BC. Legend has it that the Emperor Huangdi invented that calendar in 2637 BC. The People’s
Republic of China uses the Gregorian calendar for civil purposes. The Chinese calendar is used for
determining festivals.

The **Julian Date** system is another type of calendar, unrelated to the Julian calendar though it is con-
fusingly named similarly to that calendar. The Julian Date system was invented by the French scholar
Joseph Justus Scaliger (1540-1609) and probably takes its name from Scaliger’s father, the Italian
scholar Julius Caesar Scaliger (1484-1558). In the Julian Date system, each day has a sequential
number, starting from JD 0 (which is sometimes called the Julian Date). JD 0 corresponds to 1 Jan-
uary 4713 BC in the Julian calendar, or 24 November 4714 BC in the Gregorian calendar. Julian Date
counting is most often used by astronomers for labeling their nightly observations, and therefore a
date runs from noon UTC to the next noon UTC, rather than from midnight to midnight: JD 0 design-
nates the 24 hours from noon UTC on 24 November 4714 BC to noon UTC on 25 November 4714
BC.

Although PostgreSQL supports Julian Date notation for input and output of dates (and also uses Julian
dates for some internal datatype calculations), it does not observe the nicety of having dates run from
noon to noon. PostgreSQL treats a Julian Date as running from midnight to midnight.
Appendix C. SQL Key Words

Table C-1 lists all tokens that are key words in the SQL standard and in PostgreSQL 9.6.13. Background information can be found in Section 4.1.1. (For space reasons, only the latest two versions of the SQL standard, and SQL-92 for historical comparison, are included. The differences between those and the other intermediate standard versions are small.)

SQL distinguishes between reserved and non-reserved key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Non-reserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most non-reserved key words are actually the names of built-in tables and functions specified by SQL. The concept of non-reserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the PostgreSQL parser life is a bit more complicated. There are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved in PostgreSQL, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

In Table C-1 in the column for PostgreSQL we classify as “non-reserved” those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise non-reserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Labeled “reserved” are those tokens that are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an “AS” column label name.

As a general rule, if you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

It is important to understand before studying Table C-1 that the fact that a key word is not reserved in PostgreSQL does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

Appendix D. SQL Conformance

This section attempts to outline to what extent PostgreSQL conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. PostgreSQL development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The PostgreSQL core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for PostgreSQL.

PostgreSQL supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, PostgreSQL conforms to at least 160. In addition, there is a long list of
supported optional features. It might be worth noting that at the time of writing, no current version of
any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that PostgreSQL supports, followed
by a list of the features defined in SQL:2011 which are not yet supported in PostgreSQL. Both of
these lists are approximate: There might be minor details that are nonconforming for a feature that is
listed as supported, and large parts of an unsupported feature might in fact be implemented. The main
body of the documentation always contains the most accurate information about what does and does
not work.

Note: Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature
is not supported, the main feature is listed as unsupported even if some other subfeatures are
supported.

### D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of PostgreSQL. In a few cases, equivalent functionality is available.

Appendix E. Release Notes

The release notes contain the significant changes in each PostgreSQL release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

A complete list of changes for each release can be obtained by viewing the Git logs for each release. The `pgsql-committers` email list records all source code changes as well. There is also a web interface that shows changes to specific files.

The name appearing next to each item represents the major developer for that item. Of course all changes involve community discussion and patch review, so each item is truly a community effort.

E.1. Release 9.6.13

**Release date:** 2019-05-09

This release contains a variety of fixes from 9.6.12. For information about new features in the 9.6 major release, see Section E.14.

E.1.1. Migration to Version 9.6.13

A dump/restore is not required for those running 9.6.X. However, if you are upgrading from a version earlier than 9.6.9, see Section E.5.

E.1.2. Changes

- Prevent row-level security policies from being bypassed via selectivity estimators (Dean Rasheed)
  
  Some of the planner’s selectivity estimators apply user-defined operators to values found in `pg_statistic` (e.g., most-common values). A leaky operator therefore can disclose some of the entries in a data column, even if the calling user lacks permission to read that column. In CVE-2017-7484 we added restrictions to forestall that, but we failed to consider the effects of row-level security. A user who has SQL permission to read a column, but who is forbidden to see certain rows due to RLS policy, might still learn something about those rows’ contents via a leaky operator. This patch further tightens the rules, allowing leaky operators to be applied to statistics data only when there is no relevant RLS policy. (CVE-2019-10130)

- Fix behavior for an `UPDATE` or `DELETE` on an inheritance tree or partitioned table in which every table can be excluded (Amit Langote, Tom Lane)

  In such cases, the query did not report the correct set of output columns when a `RETURNING` clause was present, and if there were any statement-level triggers that should be fired, it didn’t fire them.

1. https://archives.postgresql.org/pgsql-committers/
• Fix handling of explicit DEFAULT items in an INSERT ... VALUES command with multiple VALUES rows, if the target relation is an updatable view (Amit Langote, Dean Rasheed)

When the updatable view has no default for the column but its underlying table has one, a single-row INSERT ... VALUES will use the underlying table’s default. In the multi-row case, however, NULL was always used. Correct it to act like the single-row case.

• Fix CREATE VIEW to allow zero-column views (Ashutosh Sharma)

We should allow this for consistency with allowing zero-column tables. Since a table can be converted to a view, zero-column views could be created even with the restriction in place, leading to dump/reload failures.

• Add missing support for CREATE TABLE IF NOT EXISTS ... AS EXECUTE ... (Andreas Karlsson)

The combination of IF NOT EXISTS and EXECUTE should work, but the grammar omitted it.

• Ensure that sub-SELECTs appearing in row-level-security policy expressions are executed with the correct user’s permissions (Dean Rasheed)

Previously, if the table having the RLS policy was accessed via a view, such checks might be executed as the user calling the view, not as the view owner as they should be.

• Accept XML documents as valid values of type xml when xmloption is set to content, as required by SQL:2006 and later (Chapman Flack)

Previously PostgreSQL followed the SQL:2003 definition, which doesn’t allow this. But that creates a serious problem for dump/restore: there is no setting of xmloption that will accept all valid XML data. Hence, switch to the 2006 definition.

pg_dump is also modified to emit SET xmloption = content while restoring data, ensuring that dump/restore works even if the prevailing setting is document.

• Improve server’s startup-time checks for whether a pre-existing shared memory segment is still in use (Noah Misch)

The postmaster is now more likely to detect that there are still active processes from a previous postmaster incarnation, even if the postmaster.pid file has been removed.

• Avoid counting parallel workers’ transactions as separate transactions (Haribabu Kommi)

• Fix incompatibility of GIN-index WAL records (Alexander Korotkov)

A fix applied in February’s minor releases was not sufficiently careful about backwards compatibility, leading to problems if a standby server of that vintage reads GIN page-deletion WAL records generated by a primary server of a previous minor release.

• Tolerate EINVAL and ENOSYS error results, where appropriate, for fsync and sync_file_range calls (Thomas Munro, James Sewell)

The previous change to panic on file synchronization failures turns out to have been excessively paranoid for certain cases where a failure is predictable and essentially means “operation not supported”.

• Fix “failed to build any N-way joins” planner failures with lateral references leading out of FULL outer joins (Tom Lane)

• Check the appropriate user’s permissions when enforcing rules about letting a leaky operator see pg_statistic data (Dean Rasheed)

When an underlying table is being accessed via a view, consider the privileges of the view owner while deciding whether leaky operators may be applied to the table’s statistics data, rather than the
privileges of the user making the query. This makes the planner’s rules about what data is visible match up with the executor’s, avoiding unnecessarily-poor plans.

- Speed up planning when there are many equality conditions and many potentially-relevant foreign key constraints (David Rowley)
- Avoid O(N^2) performance issue when rolling back a transaction that created many tables (Tomas Vondra)
- Fix race conditions in management of dynamic shared memory (Thomas Munro)
  These could lead to “dsa_area could not attach to segment” or “cannot unpin a segment that is not pinned” errors.
- Fix race condition in which a hot-standby postmaster could fail to shut down after receiving a smart-shutdown request (Tom Lane)
- Fix possible crash when `pg_identify_object_as_address()` is given invalid input (Álvaro Herrera)
- Tighten validation of encoded SCRAM-SHA-256 and MD5 passwords (Jonathan Katz)
  A password string that had the right initial characters could be mistaken for one that is correctly hashed into SCRAM-SHA-256 or MD5 format. The password would be accepted but would be unusable later.
- Fix handling of `lc_time` settings that imply an encoding different from the database’s encoding (Juan José Santamaría Flecha, Tom Lane)
  Localized month or day names that include non-ASCII characters previously caused unexpected errors or wrong output in such locales.
- Fix incorrect `operator_precedence_warning` checks involving unary minus operators (Rikard Falkeborn)
- Disallow NaN as a value for floating-point server parameters (Tom Lane)
- Rearrange `pg_class REINDEX` processing to avoid assertion failures when reindexing individual indexes of `pg_class` (Andres Freund, Tom Lane)
- Fix planner assertion failure for parameterized dummy paths (Tom Lane)
- Insert correct test function in the result of `SnapBuildInitialSnapshot()` (Antonin Houska)
  No core code cares about this, but some extensions do.
- Fix intermittent “could not reattach to shared memory” session startup failures on Windows (Noah Misch)
  A previously unrecognized source of these failures is creation of thread stacks for a process’s default thread pool. Arrange for such stacks to be allocated in a different memory region.
- Fix error detection in directory scanning on Windows (Konstantin Knizhnik)
  Errors, such as lack of permissions to read the directory, were not detected or reported correctly; instead the code silently acted as though the directory were empty.
- Fix grammar problems in ecpg (Tom Lane)
  A missing semicolon led to mistranslation of `SET variable = DEFAULT` (but not `SET variable TO DEFAULT`) in ecpg programs, producing syntactically invalid output that the server would reject. Additionally, in a `DROP TYPE` or `DROP DOMAIN` command that listed multiple type names, only the first type name was actually processed.
- Sync ecpg’s syntax for `CREATE TABLE AS` with the server’s (Daisuke Higuchi)
Appendix E. Release Notes

• Fix possible buffer overruns in ecpg’s processing of include filenames (Liu Huailing, Fei Wu)
• Avoid crash in contrib/vacuumlo if an lo_unlink() call failed (Tom Lane)
• Sync our copy of the timezone library with IANA tzcode release 2019a (Tom Lane)
  This corrects a small bug in zic that caused it to output an incorrect year-2440 transition in the Africa/Casablanca zone, and adds support for zic’s new -r option.
• Update time zone data files to tzdata release 2019a for DST law changes in Palestine and Metlakatla, plus historical corrections for Israel.
  Etc/UCT is now a backward-compatibility link to Etc/UTC, instead of being a separate zone that generates the abbreviation UCT, which nowadays is typically a typo. PostgreSQL will still accept UCT as an input zone abbreviation, but it won’t output it.

Release date: 2019-02-14

This release contains a variety of fixes from 9.6.11. For information about new features in the 9.6 major release, see Section E.14.

E.2.1. Migration to Version 9.6.12

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see Section E.5.

E.2.2. Changes

• By default, panic instead of retrying after fsync() failure, to avoid possible data corruption (Craig Ringer, Thomas Munro)
  Some popular operating systems discard kernel data buffers when unable to write them out, reporting this as fsync() failure. If we reissue the fsync() request it will succeed, but in fact the data has been lost, so continuing risks database corruption. By raising a panic condition instead, we can replay from WAL, which may contain the only remaining copy of the data in such a situation. While this is surely ugly and inefficient, there are few alternatives, and fortunately the case happens very rarely.
  A new server parameter data_sync_retry has been added to control this; if you are certain that your kernel does not discard dirty data buffers in such scenarios, you can set data_sync_retry to on to restore the old behavior.
• Include each major release branch’s release notes in the documentation for only that branch, rather than that branch and all later ones (Tom Lane)
  The duplication induced by the previous policy was getting out of hand. Our plan is to provide a full archive of release notes on the project’s web site, but not duplicate it within each release.
• Avoid possible deadlock when acquiring multiple buffer locks (Nishant Fnu)
• Avoid deadlock between hot-standby queries and replay of GIN index page deletion (Alexander Korotkov)
• Fix possible crashes in logical replication when index expressions or predicates are in use (Peter Eisentraut)
• Avoid useless and expensive logical decoding of TOAST data during a table rewrite (Tomas Vondra)
• Fix logic for stopping a subset of WAL senders when synchronous replication is enabled (Paul Guo, Michael Paquier)
• Avoid possibly writing an incorrect replica identity field in a tuple deletion WAL record (Stas Kelvich)
• Make the archiver prioritize WAL history files over WAL data files while choosing which file to archive next (David Steele)
• Fix possible crash in UPDATE with a multiple SET clause using a sub-SELECT as source (Tom Lane)
• Avoid crash if libxml2 returns a null error message (Sergio Conde Gómez)
• Fix spurious grouping-related parser errors caused by inconsistent handling of collation assignment (Andrew Gierth)
In some cases, expressions that should be considered to match were not seen as matching, if they included operations on collatable data types.
• Check whether the comparison function underlying LEAST() or GREATEST() is leakproof, rather than just assuming it is (Tom Lane)
Actual information leaks from btree comparison functions are typically hard to provoke, but in principle they could happen.
• Fix incorrect planning of queries involving nested loops both above and below a Gather plan node (Tom Lane)
If both levels of nestloop needed to pass the same variable into their right-hand sides, an incorrect plan would be generated.
• Fix incorrect planning of queries in which a lateral reference must be evaluated at a foreign table scan (Tom Lane)
• Fix corner-case underestimation of the cost of a merge join (Tom Lane)
The planner could prefer a merge join when the outer key range is much smaller than the inner key range, even if there are so many duplicate keys on the inner side that this is a poor choice.
• Avoid O(N^2) planning time growth when a query contains many thousand indexable clauses (Tom Lane)
• Improve ANALYZE’s handling of concurrently-updated rows (Jeff Janes, Tom Lane)
Previously, rows deleted by an in-progress transaction were omitted from ANALYZE’s sample, but this has been found to lead to more inconsistency than including them would do. In effect, the sample now corresponds to an MVCC snapshot as of ANALYZE’s start time.
• Make TRUNCATE ignore inheritance child tables that are temporary tables of other sessions (Amit Langote, Michael Paquier)
This brings TRUNCATE into line with the behavior of other commands. Previously, such cases usually ended in failure.
• Fix TRUNCATE to update the statistics counters for the right table (Tom Lane)
If the truncated table had a TOAST table, that table’s counters were reset instead.
• Process ALTER TABLE ONLY ADD COLUMN IF NOT EXISTS correctly (Greg Stark)
• Allow UNLISTEN in hot-standby mode (Shay Rojansky)
This is necessarily a no-op, because `LISTEN` isn’t allowed in hot-standby mode; but allowing the dummy operation simplifies session-state-reset logic in clients.

- **Fix missing role dependencies in some schema and data type permissions lists (Tom Lane)**
  In some cases it was possible to drop a role to which permissions had been granted. This caused no immediate problem, but a subsequent dump/reload or upgrade would fail, with symptoms involving attempts to grant privileges to all-numeric role names.

- **Ensure relation caches are updated properly after adding or removing foreign key constraints (Álvaro Herrera)**
  This oversight could result in existing sessions failing to enforce a newly-created constraint, or continuing to enforce a dropped one.

- **Ensure relation caches are updated properly after renaming constraints (Amit Langote)**

- **Make autovacuum more aggressive about removing leftover temporary tables, and also remove leftover temporary tables during `DISCARD TEMP` (Álvaro Herrera)**
  This helps ensure that remnants from a crashed session are cleaned up more promptly.

- **Fix replay of GiST index micro-vacuum operations so that concurrent hot-standby queries do not see inconsistent state (Alexander Korotkov)**

- **Prevent empty GIN index pages from being reclaimed too quickly, causing failures of concurrent searches (Andrey Borodin, Alexander Korotkov)**

- **Fix edge-case failures in float-to-integer coercions (Andrew Gierth, Tom Lane)**
  Values very slightly above the maximum valid integer value might not be rejected, and then would overflow, producing the minimum valid integer instead. Also, values that should round to the minimum or maximum integer value might be incorrectly rejected.

- **When making a PAM authentication request, don’t set the `PAM_RHOST` variable if the connection is via a Unix socket (Thomas Munro)**
  Previously that variable would be set to `[local]`, which is at best unhelpful, since it’s supposed to be a host name.

- **Disallow setting `client_min_messages` higher than `ERROR` (Jonah Harris, Tom Lane)**
  Previously, it was possible to set this variable to `FATAL` or `PANIC`, which had the effect of suppressing transmission of ordinary error messages to the client. However, that’s contrary to guarantees that are given in the PostgreSQL wire protocol specification, and it caused some clients to become very confused. In released branches, fix this by silently treating such settings as meaning `ERROR` instead. Version 12 and later will reject those alternatives altogether.

- **Fix ecpglib to use `uselocale()` or `_configthreadlocale()` in preference to `setlocale()` (Michael Meskes, Tom Lane)**
  Since `setlocale()` is not thread-local, and might not even be thread-safe, the previous coding caused problems in multi-threaded ecpg applications.

- **Fix incorrect results for numeric data passed through an ecpg SQLDA (SQL Descriptor Area) (Daisuke Higuchi)**
  Values with leading zeroes were not copied correctly.

- **Fix psql’s `\g target` meta-command to work with `COPY TO STDOUT` (Daniel Vérité)**
  Previously, the `target` option was ignored, so that the copy data always went to the current query output target.

- **Make psql’s LaTeX output formats render special characters properly (Tom Lane)**
Backslash and some other ASCII punctuation characters were not rendered correctly, leading to document syntax errors or wrong characters in the output.

- Fix pg_dump’s handling of materialized views with indirect dependencies on primary keys (Tom Lane)

  This led to mis-labeling of such views’ dump archive entries, causing harmless warnings about “archive items not in correct section order”; less harmlessly, selective-restore options depending on those labels, such as --section, might misbehave.

- Avoid null-pointer-dereference crash on some platforms when pg_dump or pg_restore tries to report an error (Tom Lane)

- Fix contrib/hstore to calculate correct hash values for empty hstore values that were created in version 8.4 or before (Andrew Gierth)

  The previous coding did not give the same result as for an empty hstore value created by a newer version, thus potentially causing wrong results in hash joins or hash aggregation. It is advisable to reindex any hash indexes built on hstore columns, if the table might contain data that was originally stored as far back as 8.4 and was never dumped/reloaded since then.

- Avoid crashes and excessive runtime with large inputs to contrib/intarray’s gist__int_ops index support (Andrew Gierth)

- Support new Makefile variables PG_CFLAGS, PG_CXXFLAGS, and PG_LDFLAGS in pgxs builds (Christoph Berg)

  This simplifies customization of extension build processes.

- Fix Perl-coded build scripts to not assume “.” is in the search path, since recent Perl versions don’t include that (Andrew Dunstan)

- Fix server command-line option parsing problems on OpenBSD (Tom Lane)

- Relocate call of set_rel_pathlist_hook so that extensions can use it to supply partial paths for parallel queries (KaiGai Kohei)

  This is not expected to affect existing use-cases.

- Update time zone data files to tzdata release 2018i for DST law changes in Kazakhstan, Metlakatla, and Sao Tome and Principe. Kazakhstan’s Qyzylorda zone is split in two, creating a new zone Asia/Qostanay, as some areas did not change UTC offset. Historical corrections for Hong Kong and numerous Pacific islands.

E.3. Release 9.6.11

Release date: 2018-11-08

This release contains a variety of fixes from 9.6.10. For information about new features in the 9.6 major release, see Section E.14.

E.3.1. Migration to Version 9.6.11

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.9, see Section E.5.
E.3.2. Changes

- Fix corner-case failures in `hasFooPrivilege()` family of functions (Tom Lane)
  
  Return NULL rather than throwing an error when an invalid object OID is provided. Some of these functions got that right already, but not all. `has_column_privilege()` was additionally capable of crashing on some platforms.

- Avoid O(N^2) slowdown in regular expression match/split functions on long strings (Andrew Gierth)

- Fix parsing of standard multi-character operators that are immediately followed by a comment or `+` or `-` (Andrew Gierth)
  
  This oversight could lead to parse errors, or to incorrect assignment of precedence.

- Avoid O(N^3) slowdown in lexers for long strings of `+` or `-` characters (Andrew Gierth)

- Fix mis-execution of SubPlains when the outer query is being scanned backwards (Andrew Gierth)

- Fix failure of `UPDATE/DELETE ... WHERE CURRENT OF ...` after rewinding the referenced cursor (Tom Lane)
  
  A cursor that scans multiple relations (particularly an inheritance tree) could produce wrong behavior if rewound to an earlier relation.

- Fix `EvalPlanQual` to handle conditionally-executed InitPlans properly (Andrew Gierth, Tom Lane)
  
  This resulted in hard-to-reproduce crashes or wrong answers in concurrent updates, if they contained code such as an uncorrelated sub-`SELECT` inside a `CASE` construct.

- Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane, Kenji Uno)
  
  This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.

- Disallow pushing sub-`SELECTs` containing window functions, `LIMIT`, or `OFFSET` to parallel workers (Amit Kapila)
  
  Such cases could result in inconsistent behavior due to different workers getting different answers, as a result of indeterminacy due to row-ordering variations.

- Ensure that sequences owned by a foreign table are processed by `ALTER OWNER` on the table (Peter Eisentraut)
  
  The ownership change should propagate to such sequences as well, but this was missed for foreign tables.

- Ensure that the server will process already-received `NOTIFY` and `SIGTERM` interrupts before waiting for client input (Jeff Janes, Tom Lane)

- Fix over-allocation of space for `array_out()`’s result string (Keiichi Hirobe)

- Fix memory leak in repeated SP-GiST index scans (Tom Lane)
  
  This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.

- Ensure that `ApplyLogicalMappingFile()` closes the mapping file when done with it (Tomas Vondra)
  
  Previously, the file descriptor was leaked, eventually resulting in failures during logical decoding.
Appendix E. Release Notes

- Fix logical decoding to handle cases where a mapped catalog table is repeatedly rewritten, e.g. by `VACUUM FULL` (Andres Freund)
- Prevent starting the server with `wal_level` set to too low a value to support an existing replication slot (Andres Freund)
- Avoid crash if a utility command causes infinite recursion (Tom Lane)
- When initializing a hot standby, cope with duplicate XIDs caused by two-phase transactions on the master (Michael Paquier, Konstantin Knizhnik)
- Fix event triggers to handle nested `ALTER TABLE` commands (Michael Paquier, Álvaro Herrera)
- Propagate parent process’s transaction and statement start timestamps to parallel workers (Konstantin Knizhnik)
  This prevents misbehavior of functions such as `transaction_timestamp()` when executed in a worker.
- Fix transfer of expanded datums to parallel workers so that alignment is preserved, preventing crashes on alignment-picky platforms (Tom Lane, Amit Kapila)
- Fix WAL file recycling logic to work correctly on standby servers (Michael Paquier)
  Depending on the setting of `archive_mode`, a standby might fail to remove some WAL files that could be removed.
- Fix handling of commit-timestamp tracking during recovery (Masahiko Sawada, Michael Paquier)
  If commit timestamp tracking has been turned on or off, recovery might fail due to trying to fetch the commit timestamp for a transaction that did not record it.
- Randomize the `random()` seed in bootstrap and standalone backends, and in `initdb` (Noah Misch)
  The main practical effect of this change is that it avoids a scenario where `initdb` might mistakenly conclude that POSIX shared memory is not available, due to name collisions caused by always using the same random seed.
- Allow DSM allocation to be interrupted (Chris Travers)
- Avoid failure in a parallel worker when loading an extension that tries to access system caches within its init function (Thomas Munro)
  We don’t consider that to be good extension coding practice, but it mostly worked before parallel query, so continue to support it for now.
- Properly handle turning `full_page_writes` on dynamically (Kyotaro Horiguchi)
- Fix possible crash due to double `free()` during SP-GiST rescan (Andrew Gierth)
- Avoid possible buffer overrun when replaying GIN page recompression from WAL (Alexander Korotkov, Sivasubramanian Ramasubramanian)
- Fix missed fsync of a replication slot’s directory (Konstantin Knizhnik, Michael Paquier)
- Fix unexpected timeouts when using `wal_sender_timeout` on a slow server (Noah Misch)
- Ensure that hot standby processes use the correct WAL consistency point (Alexander Kukushkin, Michael Paquier)
  This prevents possible misbehavior just after a standby server has reached a consistent database state during WAL replay.
- Ensure background workers are stopped properly when the postmaster receives a fast-shutdown request before completing database startup (Alexander Kukushkin)
Appendix E. Release Notes

- Update the free space map during WAL replay of page all-visible/frozen flag changes (Álvaro Herrera)

  Previously we were not careful about this, reasoning that the FSM is not critical data anyway. However, if it’s sufficiently out of date, that can result in significant performance degradation after a standby has been promoted to primary. The FSM will eventually be healed by updates, but we’d like it to be good sooner, so work harder at maintaining it during WAL replay.

- Avoid premature release of parallel-query resources when query end or tuple count limit is reached (Amit Kapila)

  It’s only okay to shut down the executor at this point if the caller cannot demand backwards scan afterwards.

- Don’t run atexit callbacks when servicing SIGQUIT (Heikki Linnakangas)

- Don’t record foreign-server user mappings as members of extensions (Tom Lane)

  If CREATE USER MAPPING is executed in an extension script, an extension dependency was created for the user mapping, which is unexpected. Roles can’t be extension members, so user mappings shouldn’t be either.

- Make sysloggger more robust against failures in opening CSV log files (Tom Lane)

- Fix psql, as well as documentation examples, to call PQconsumeInput() before each PQnotifies() call (Tom Lane)

  This fixes cases in which psql would not report receipt of a NOTIFY message until after the next command.

- Fix possible inconsistency in pg_dump’s sorting of dissimilar object names (Jacob Champion)

- Ensure that pg_restore will schema-qualify the table name when emitting DISABLE/ENABLE TRIGGER commands (Tom Lane)

  This avoids failures due to the new policy of running restores with restrictive search path.

- Fix pg_upgrade to handle event triggers in extensions correctly (Haribabu Kommi)

  pg_upgrade failed to preserve an event trigger’s extension-membership status.

- Fix pg_upgrade’s cluster state check to work correctly on a standby server (Bruce Momjian)

- Enforce type cube’s dimension limit in all contrib/cube functions (Andrey Borodin)

  Previously, some cube-related functions could construct values that would be rejected by cube_in(), leading to dump/reload failures.

- In contrib/postgres_fdw, don’t try to ship a variable-free ORDER BY clause to the remote server (Andrew Gierth)

- Fix contrib/unaccent’s unaccent() function to use the unaccent text search dictionary that is in the same schema as the function (Tom Lane)

  Previously it tried to look up the dictionary using the search path, which could fail if the search path has a restrictive value.

- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)

  Adjust configure to add an --sysroot switch to CPPFLAGS; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific sysroot used can be overridden at configure time or build time by setting the PG_SYSROOT variable in the arguments of configure or make.

  It is now recommended that Perl-related extensions write $ perl_includespec rather than -I$(perl_archlibexp)/CORE in their compiler flags. The latter continues to work on most platforms, but not recent macOS.
Also, it should no longer be necessary to specify --with-tclconfig manually to get PL/Tcl to build on recent macOS releases.

- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)
  Perl no longer includes the current directory in its search path by default; work around that.
- On Windows, allow the regression tests to be run by an Administrator account (Andrew Dunstan)
  To do this safely, pg_regress now gives up any such privileges at startup.
- Allow btree comparison functions to return INT_MIN (Tom Lane)
  Up to now, we’ve forbidden datatype-specific comparison functions from returning INT_MIN, which allows callers to invert the sort order just by negating the comparison result. However, this was never safe for comparison functions that directly return the result of memcmp(), strcmp(), etc, as POSIX doesn’t place any such restriction on those functions. At least some recent versions of memcmp() can return INT_MIN, causing incorrect sort ordering. Hence, we’ve removed this restriction. Callers must now use the INVERT_COMPARE_RESULT() macro if they wish to invert the sort order.
- Fix recursion hazard in shared-invalidation message processing (Tom Lane)
  This error could, for example, result in failure to access a system catalog or index that had just been processed by VACUUM FULL.
  This change adds a new result code for LockAcquire, which might possibly affect external callers of that function, though only very unusual usage patterns would have an issue with it. The API of LockAcquireExtended is also changed.
- Save and restore SPI’s global variables during SPI_connect() and SPI_finish() (Chapman Flack, Tom Lane)
  This prevents possible interference when one SPI-using function calls another.
- Avoid using potentially-under-aligned page buffers (Tom Lane)
  Invent new union types PGAignedBlock and PGAignedXLogBlock, and use these in place of plain char arrays, ensuring that the compiler can’t place the buffer at a misaligned start address. This fixes potential core dumps on alignment-picky platforms, and may improve performance even on platforms that allow misalignment.
- Make src/port/snprintf.c follow the C99 standard’s definition of snprintf()’s result value (Tom Lane)
  On platforms where this code is used (mostly Windows), its pre-C99 behavior could lead to failure to detect buffer overrun, if the calling code assumed C99 semantics.
- When building on i386 with the clang compiler, require -msse2 to be used (Andres Freund)
  This avoids problems with missed floating point overflow checks.
- Fix configure’s detection of the result type of strerror_r() (Tom Lane)
  The previous coding got the wrong answer when building with icc on Linux (and perhaps in other cases), leading to libpq not returning useful error messages for system-reported errors.
- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.
Appendix E. Release Notes

E.4. Release 9.6.10

Release date: 2018-08-09

This release contains a variety of fixes from 9.6.9. For information about new features in the 9.6 major release, see Section E.14.

E.4.1. Migration to Version 9.6.10

A dump/restore is not required for those running 9.6.X. However, if you are upgrading from a version earlier than 9.6.9, see Section E.5.

E.4.2. Changes

• Fix failure to reset libpq’s state fully between connection attempts (Tom Lane)

   An unprivileged user of dblink or postgres_fdw could bypass the checks intended to prevent use of server-side credentials, such as a ~/pgpass file owned by the operating-system user running the server. Servers allowing peer authentication on local connections are particularly vulnerable. Other attacks such as SQL injection into a postgres_fdw session are also possible. Attacking postgres_fdw in this way requires the ability to create a foreign server object with selected connection parameters, but any user with access to dblink could exploit the problem. In general, an attacker with the ability to select the connection parameters for a libpq-using application could cause mischief, though other plausible attack scenarios are harder to think of. Our thanks to Andrew Krasichkov for reporting this issue. (CVE-2018-10915)

• Fix INSERT ... ON CONFLICT UPDATE through a view that isn’t just SELECT * FROM ...

   (Dean Rasheed, Amit Langote)

   Erroneous expansion of an updatable view could lead to crashes or “attribute ... has the wrong type” errors, if the view’s SELECT list doesn’t match one-to-one with the underlying table’s columns. Furthermore, this bug could be leveraged to allow updates of columns that an attacking user lacks UPDATE privilege for, if that user has INSERT and UPDATE privileges for some other column(s) of the table. Any user could also use it for disclosure of server memory. (CVE-2018-10925)

• Ensure that updates to the relfrozenxid and relminxid values for “nailed” system catalogs are processed in a timely fashion (Andres Freund)

   Overoptimistic caching rules could prevent these updates from being seen by other sessions, leading to spurious errors and/or data corruption. The problem was significantly worse for shared catalogs, such as pg_authid, because the stale cache data could persist into new sessions as well as existing ones.

• Fix case where a freshly-promoted standby crashes before having completed its first post-recovery checkpoint (Michael Paquier, Kyotaro Horiguchi, Pavan Deolasee, Alvaro Herrera)

   This led to a situation where the server did not think it had reached a consistent database state during subsequent WAL replay, preventing restart.

• Avoid emitting a bogus WAL record when recycling an all-zero btree page (Amit Kapila)

   This mistake has been seen to cause assertion failures, and potentially it could result in unnecessary query cancellations on hot standby servers.

• During WAL replay, guard against corrupted record lengths exceeding 1GB (Michael Paquier)
Appendix E. Release Notes

Treat such a case as corrupt data. Previously, the code would try to allocate space and get a hard error, making recovery impossible.

- When ending recovery, delay writing the timeline history file as long as possible (Heikki Linnakan-gas)
  This avoids some situations where a failure during recovery cleanup (such as a problem with a two-phase state file) led to inconsistent timeline state on-disk.
- Improve performance of WAL replay for transactions that drop many relations (Fujii Masao)
  This change reduces the number of times that shared buffers are scanned, so that it is of most benefit when that setting is large.
- Improve performance of lock releasing in standby server WAL replay (Thomas Munro)
- Make logical WAL senders report streaming state correctly (Simon Riggs, Sawada Masahiko)
  The code previously mis-detected whether or not it had caught up with the upstream server.
- Fix bugs in snapshot handling during logical decoding, allowing wrong decoding results in rare cases (Arseny Sher, Álvaro Herrera)
- Ensure a table’s cached index list is correctly rebuilt after an index creation fails partway through (Peter Geoghegan)
  Previously, the failed index’s OID could remain in the list, causing problems later in the same session.
- Fix mishandling of empty uncompressed posting list pages in GIN indexes (Sivasubramanian Ramasubramanian, Alexander Korotkov)
  This could result in an assertion failure after pg_upgrade of a pre-9.4 GIN index (9.4 and later will not create such pages).
- Ensure that VACUUM will respond to signals within btree page deletion loops (Andres Freund)
  Corrupted btree indexes could result in an infinite loop here, and that previously wasn’t interruptible without forcing a crash.
- Fix misoptimization of equivalence classes involving composite-type columns (Tom Lane)
  This resulted in failure to recognize that an index on a composite column could provide the sort order needed for a mergejoin on that column.
- Fix planner to avoid “ORDER/GROUP BY expression not found in targetlist” errors in some queries with set-returning functions (Tom Lane)
- Fix SQL-standard FETCH FIRST syntax to allow parameters ($n$), as the standard expects (Andrew Gierth)
- Fix EXPLAIN’s accounting for resource usage, particularly buffer accesses, in parallel workers (Amit Kapila, Robert Haas)
- Fix failure to schema-qualify some object names in getObjectDescription output (Kyotaro Horiguchi, Tom Lane)
  Names of collations, conversions, and text search objects were not schema-qualified when they should be.
- Fix CREATE AGGREGATE type checking so that parallelism support functions can be attached to variadic aggregates (Alexey Bashtanov)
- Widen COPY FROM’s current-line-number counter from 32 to 64 bits (David Rowley)
Appendix E. Release Notes

This avoids two problems with input exceeding 4G lines: COPY FROM WITH HEADER would drop a line every 4G lines, not only the first line, and error reports could show a wrong line number.

- Add a string freeing function to ecpg’s pgtypes library, so that cross-module memory management problems can be avoided on Windows (Takayuki Tsunakawa)

  On Windows, crashes can ensue if the free call for a given chunk of memory is not made from the same DLL that malloc'd the memory. The pgtypes library sometimes returns strings that it expects the caller to free, making it impossible to follow this rule. Add a PGTYPESchar_free() function that just wraps free, allowing applications to follow this rule.

- Fix ecpg’s support for long long variables on Windows, as well as other platforms that declare strtoll/strtoull nonstandardly or not at all (Dang Minh Huong, Tom Lane)

- Fix misidentification of SQL statement type in PL/pgSQL, when a rule change causes a change in the semantics of a statement intra-session (Tom Lane)

  This error led to assertion failures, or in rare cases, failure to enforce the INTO STRICT option as expected.

- Fix password prompting in client programs so that echo is properly disabled on Windows when stdin is not the terminal (Matthew Stickney)

- Further fix mis-quoting of values for list-valued GUC variables in dumps (Tom Lane)

  The previous fix for quoting of search_path and other list-valued variables in pg_dump output turned out to misbehave for empty-string list elements, and it risked truncation of long file paths.

- Fix pg_dump’s failure to dump REPLICA IDENTITY properties for constraint indexes (Tom Lane)

  Manually created unique indexes were properly marked, but not those created by declaring UNIQUE or PRIMARY KEY constraints.

- Make pg_upgrade check that the old server was shut down cleanly (Bruce Momjian)

  The previous check could be fooled by an immediate-mode shutdown.

- Fix contrib/hstore_plperl to look through Perl scalar references, and to not crash if it doesn’t find a hash reference where it expects one (Tom Lane)

- Fix crash in contrib/ltree’s lca() function when the input array is empty (Pierre Ducroquet)

- Fix various error-handling code paths in which an incorrect error code might be reported (Michael Paquier, Tom Lane, Magnus Hagander)

- Rearrange makefiles to ensure that programs link to freshly-built libraries (such as libpq.so) rather than ones that might exist in the system library directories (Tom Lane)

  This avoids problems when building on platforms that supply old copies of PostgreSQL libraries.

- Update time zone data files to tzdata release 2018e for DST law changes in North Korea, plus historical corrections for Czechoslovakia.

  This update includes a redefinition of “daylight savings” in Ireland, as well as for some past years in Namibia and Czechoslovakia. In those jurisdictions, legally standard time is observed in summer, and daylight savings time in winter, so that the daylight savings offset is one hour behind standard time not one hour ahead. This does not affect either the actual UTC offset or the timezone abbreviations in use; the only known effect is that the is_dst column in the pg_timezone_names view will now be true in winter and false in summer in these cases.
Appendix E. Release Notes

E.5. Release 9.6.9

Release date: 2018-05-10

This release contains a variety of fixes from 9.6.8. For information about new features in the 9.6 major release, see Section E.14.

E.5.1. Migration to Version 9.6.9

A dump/restore is not required for those running 9.6.X.

However, if you use the adminpack extension, you should update it as per the first changelog entry below.

Also, if the function marking mistakes mentioned in the second and third changelog entries below affect you, you will want to take steps to correct your database catalogs.

Also, if you are upgrading from a version earlier than 9.6.8, see Section E.6.

E.5.2. Changes

• Remove public execute privilege from contrib/adminpack’s pg_logfile_rotate() function (Stephen Frost)

pg_logfile_rotate() is a deprecated wrapper for the core function pg_rotate_logfile(). When that function was changed to rely on SQL privileges for access control rather than a hard-coded superuser check, pg_logfile_rotate() should have been updated as well, but the need for this was missed. Hence, if adminpack is installed, any user could request a logfile rotation, creating a minor security issue.

After installing this update, administrators should update adminpack by performing ALTER EXTENSION adminpack UPDATE in each database in which adminpack is installed. (CVE-2018-1115)

• Fix incorrect volatility markings on a few built-in functions (Thomas Munro, Tom Lane)

The functions query_to_xml, cursor_to_xml, cursor_to_xmlschema, query_to_xmlschema, and query_to_xml_and_xmlschema should be marked volatile because they execute user-supplied queries that might contain volatile operations. They were not, leading to a risk of incorrect query optimization. This has been repaired for new installations by correcting the initial catalog data, but existing installations will continue to contain the incorrect markings. Practical use of these functions seems to pose little hazard, but in case of trouble, it can be fixed by manually updating these functions’ pg_proc entries, for example ALTER FUNCTION pg_catalog.query_to_xml(text, boolean, boolean, text) VOLATILE. (Note that that will need to be done in each database of the installation.) Another option is to pg_upgrade the database to a version containing the corrected initial data.

• Fix incorrect parallel-safety markings on a few built-in functions (Thomas Munro, Tom Lane)

The functions brin_summarize_new_values, gin_clean_pending_list, cursor_to_xml, cursor_to_xmlschema, ts_rewrite, ts_stat, and binary_upgrade_create_empty_extension should be marked parallel-unsafe; some because they perform database modifications directly, and others because they execute user-supplied queries that might do so. They were marked parallel-restricted instead, leading to a risk of unexpected query errors. This has been repaired for new
installations by correcting the initial catalog data, but existing installations will continue
to contain the incorrect markings. Practical use of these functions seems to pose little
hazard unless force_parallel_mode is turned on. In case of trouble, it can be fixed
by manually updating these functions' pg_proc entries, for example ALTER FUNCTION
pg_catalog.brin_summarize_new_values(regclass) PARALLEL UNSAFE. (Note that
that will need to be done in each database of the installation.) Another option is to pg_upgrade the
database to a version containing the corrected initial data.

- Avoid re-using TOAST value OIDs that match dead-but-not-yet-vacuumed TOAST entries (Pavan
  Deolasee)
  Once the OID counter has wrapped around, it’s possible to assign a TOAST value whose OID
  matches a previously deleted entry in the same TOAST table. If that entry were not yet vacuumed
  away, this resulted in “unexpected chunk number 0 (expected 1) for toast value nnnnn” errors,
  which would persist until the dead entry was removed by VACUUM. Fix by not selecting such OIDs
  when creating a new TOAST entry.

- Change ANALYZE’s algorithm for updating pg_class.reltuples (David Gould)
  Previously, pages not actually scanned by ANALYZE were assumed to retain their old tuple density.
  In a large table where ANALYZE samples only a small fraction of the pages, this meant that the
  overall tuple density estimate could not change very much, so that reltuples would change nearly
  proportionally to changes in the table’s physical size (relpages) regardless of what was actually
  happening in the table. This has been observed to result in reltuples becoming so much larger
  than reality as to effectively shut off autovacuuming. To fix, assume that ANALYZE’s sample is a
  statistically unbiased sample of the table (as it should be), and just extrapolate the density observed
  within those pages to the whole table.

- Avoid deadlocks in concurrent CREATE INDEX CONCURRENTLY commands that are run under
  SERIALIZABLE or REPEATABLE READ transaction isolation (Tom Lane)

- Fix possible slow execution of REFRESH MATERIALIZED VIEW CONCURRENTLY (Thomas
  Munro)

- Fix UPDATE/DELETE ... WHERE CURRENT OF to not fail when the referenced cursor uses an
  index-only-scan plan (Yugo Nagata, Tom Lane)

- Fix incorrect planning of join clauses pushed into parameterized paths (Andrew Gierth, Tom Lane)
  This error could result in misclassifying a condition as a “join filter” for an outer join when it should
  be a plain “filter” condition, leading to incorrect join output.

- Fix possibly incorrect generation of an index-only-scan plan when the same table column appears
  in multiple index columns, and only some of those index columns use operator classes that can
  return the column value (Kyotaro Horiguchi)

- Fix misoptimization of CHECK constraints having provably-NULL subclauses of top-level AND/OR
  conditions (Tom Lane, Dean Rasheed)
  This could, for example, allow constraint exclusion to exclude a child table that should not be
  excluded from a query.

- Fix executor crash due to double free in some GROUPING SET usages (Peter Geoghegan)

- Avoid crash if a table rewrite event trigger is added concurrently with a command that could call
  such a trigger (Álvaro Herrera, Andrew Gierth, Tom Lane)

- Avoid failure if a query-cancel or session-termination interrupt occurs while committing a prepared
  transaction (Stas Kelvich)

- Fix query-lifespan memory leakage in repeatedly executed hash joins (Tom Lane)
• Fix possible leak or double free of visibility map buffer pins (Amit Kapila)

• Avoid spuriously marking pages as all-visible (Dan Wood, Pavan Deolasee, Álvaro Herrera)
  This could happen if some tuples were locked (but not deleted). While queries would still function correctly, vacuum would normally ignore such pages, with the long-term effect that the tuples were never frozen. In recent releases this would eventually result in errors such as “found multixact nnnnn from before relminmxid nnnnn”.

• Fix overly strict sanity check in heap_prepare_freeze_tuple (Álvaro Herrera)
  This could result in incorrect “cannot freeze committed xmax” failures in databases that have been pg_upgrade’d from 9.2 or earlier.

• Prevent dangling-pointer dereference when a C-coded before-update row trigger returns the “old” tuple (Rushabh Lathia)

• Reduce locking during autovacuum worker scheduling (Jeff Janes)
  The previous behavior caused drastic loss of potential worker concurrency in databases with many tables.

• Ensure client hostname is copied while copying pg_stat_activity data to local memory (Edmund Horner)
  Previously the supposedly-local snapshot contained a pointer into shared memory, allowing the client hostname column to change unexpectedly if any existing session disconnected.

• Fix incorrect processing of multiple compound affixes in ispell dictionaries (Arthur Zakirov)

• Fix collation-aware searches (that is, indexscans using inequality operators) in SP-GiST indexes on text columns (Tom Lane)
  Such searches would return the wrong set of rows in most non-C locales.

• Prevent query-lifespan memory leakage with SP-GiST operator classes that use traversal values (Anton Dignös)

• Count the number of index tuples correctly during initial build of an SP-GiST index (Tomas Vondra)
  Previously, the tuple count was reported to be the same as that of the underlying table, which is wrong if the index is partial.

• Count the number of index tuples correctly during vacuuming of a GiST index (Andrey Borodin)
  Previously it reported the estimated number of heap tuples, which might be inaccurate, and is certainly wrong if the index is partial.

• Fix a corner case where a streaming standby gets stuck at a WAL continuation record (Kyotaro Horiguchi)

• In logical decoding, avoid possible double processing of WAL data when a walsender restarts (Craig Ringer)

• Allow scalarltsel and scalargtssel to be used on non-core datatypes (Tomas Vondra)

• Reduce libpq’s memory consumption when a server error is reported after a large amount of query output has been collected (Tom Lane)
  Discard the previous output before, not after, processing the error message. On some platforms, notably Linux, this can make a difference in the application’s subsequent memory footprint.

• Fix double-free crashes in ecpg (Patrick Krecker, Jeevan Ladhe)

• Fix ecpg to handle long long int variables correctly in MSVC builds (Michael Meskes, Andrew Gierth)
Appendix E. Release Notes

- Fix mis-quoting of values for list-valued GUC variables in dumps (Michael Paquier, Tom Lane)
  The local_preload_libraries, session_preload_libraries, shared_preload_libraries, and temp_tablespaces variables were not correctly quoted in pg_dump output. This would cause problems if settings for these variables appeared in CREATE FUNCTION ... SET or ALTER DATABASE/ROLE ... SET clauses.

- Fix pg_recvlogical to not fail against pre-v10 PostgreSQL servers (Michael Paquier)
  A previous fix caused pg_recvlogical to issue a command regardless of server version, but it should only be issued to v10 and later servers.

- Ensure that pg_rewind deletes files on the target server if they are deleted from the source server during the run (Takayuki Tsunakawa)
  Failure to do this could result in data inconsistency on the target, particularly if the file in question is a WAL segment.

- Fix pg_rewind to handle tables in non-default tablespaces correctly (Takayuki Tsunakawa)

- Fix overflow handling in PL/pgSQL integer FOR loops (Tom Lane)
  The previous coding failed to detect overflow of the loop variable on some non-gcc compilers, leading to an infinite loop.

- Adjust PL/Python regression tests to pass under Python 3.7 (Peter Eisentraut)

- Support testing PL/Python and related modules when building with Python 3 and MSVC (Andrew Dunstan)

- Fix errors in initial build of contrib/bloom indexes (Tomas Vondra, Tom Lane)
  Fix possible omission of the table’s last tuple from the index. Count the number of index tuples correctly, in case it is a partial index.

- Rename internal b64_encode and b64_decode functions to avoid conflict with Solaris 11.4 built-in functions (Rainer Orth)

- Sync our copy of the timezone library with IANA tzcode release 2018e (Tom Lane)
  This fixes the zic timezone data compiler to cope with negative daylight-savings offsets. While the PostgreSQL project will not immediately ship such timezone data, zic might be used with timezone data obtained directly from IANA, so it seems prudent to update zic now.

- Update time zone data files to tzdata release 2018d for DST law changes in Palestine and Antarctica (Casey Station), plus historical corrections for Portugal and its colonies, as well as Enderbury, Jamaica, Turks & Caicos Islands, and Uruguay.

E.6. Release 9.6.8

Release date: 2018-03-01

This release contains a variety of fixes from 9.6.7. For information about new features in the 9.6 major release, see Section E.14.

E.6.1. Migration to Version 9.6.8

A dump/restore is not required for those running 9.6.X.
However, if you run an installation in which not all users are mutually trusting, or if you maintain an application or extension that is intended for use in arbitrary situations, it is strongly recommended that you read the documentation changes described in the first changelog entry below, and take suitable steps to ensure that your installation or code is secure.

Also, the changes described in the second changelog entry below may cause functions used in index expressions or materialized views to fail during auto-analyze, or when reloading from a dump. After upgrading, monitor the server logs for such problems, and fix affected functions.

Also, if you are upgrading from a version earlier than 9.6.7, see Section E.7.

E.6.2. Changes

- Document how to configure installations and applications to guard against search-path-dependent trojan-horse attacks from other users (Noah Misch)

  Using a `search_path` setting that includes any schemas writable by a hostile user enables that user to capture control of queries and then run arbitrary SQL code with the permissions of the attacked user. While it is possible to write queries that are proof against such hijacking, it is notationally tedious, and it’s very easy to overlook holes. Therefore, we now recommend configurations in which no untrusted schemas appear in one’s search path. Relevant documentation appears in Section 5.8.6 (for database administrators and users), Section 32.1 (for application authors), Section 36.15.1 (for extension authors), and CREATE FUNCTION (for authors of `SECURITY DEFINER` functions). (CVE-2018-1058)

- Avoid use of insecure `search_path` settings in `pg_dump` and other client programs (Noah Misch, Tom Lane)

  `pg_dump`, `pg_upgrade`, `vacuumdb` and other PostgreSQL-provided applications were themselves vulnerable to the type of hijacking described in the previous changelog entry; since these applications are commonly run by superusers, they present particularly attractive targets. To make them secure whether or not the installation as a whole has been secured, modify them to include only the `pg_catalog` schema in their `search_path` settings. Autovacuum worker processes now do the same, as well.

  In cases where user-provided functions are indirectly executed by these programs — for example, user-provided functions in index expressions — the tighter `search_path` may result in errors, which will need to be corrected by adjusting those user-provided functions to not assume anything about what search path they are invoked under. That has always been good practice, but now it will be necessary for correct behavior. (CVE-2018-1058)

- Fix misbehavior of concurrent-update rechecks with CTE references appearing in subplans (Tom Lane)

  If a CTE (WITH clause reference) is used in an InitPlan or SubPlan, and the query requires a recheck due to trying to update or lock a concurrently-updated row, incorrect results could be obtained.

- Fix planner failures with overlapping mergejoin clauses in an outer join (Tom Lane)

  These mistakes led to “left and right pathkeys do not match in mergejoin” or “outer pathkeys do not match mergeclauses” planner errors in corner cases.

- Repair `pg_upgrade`’s failure to preserve `refrozenxid` for materialized views (Tom Lane, Andres Freund)

  This oversight could lead to data corruption in materialized views after an upgrade, manifesting as “could not access status of transaction” or “found xmin from before refrozenxid” errors. The
problem would be more likely to occur in seldom-refreshed materialized views, or ones that were maintained only with `REFRESH MATERIALIZED VIEW CONCURRENTLY`.

If such corruption is observed, it can be repaired by refreshing the materialized view (without `CONCURRENTLY`).

- Fix incorrect reporting of PL/Python function names in error `CONTEXT` stacks (Tom Lane)
  An error occurring within a nested PL/Python function call (that is, one reached via a SPI query from another PL/Python function) would result in a stack trace showing the inner function’s name twice, rather than the expected results. Also, an error in a nested PL/Python `DO` block could result in a null pointer dereference crash on some platforms.

- Allow `contrib/auto_explain`’s `log_min_duration` setting to range up to `INT_MAX`, or about 24 days instead of 35 minutes (Tom Lane)

- Mark assorted GUC variables as `PGDLLIMPORT`, to ease porting extension modules to Windows (Metin Doslu)

### E.7. Release 9.6.7

**Release date:** 2018-02-08

This release contains a variety of fixes from 9.6.6. For information about new features in the 9.6 major release, see Section E.14.

#### E.7.1. Migration to Version 9.6.7

A dump/restore is not required for those running 9.6.X.

However, if you use `contrib/cube`’s `~>` operator, see the entry below about that.

Also, if you are upgrading from a version earlier than 9.6.6, see Section E.8.

#### E.7.2. Changes

- Ensure that all temporary files made by `pg_upgrade` are non-world-readable (Tom Lane, Noah Misch)

  `pg_upgrade` normally restricts its temporary files to be readable and writable only by the calling user. But the temporary file containing `pg_dumpall -g` output would be group- or world-readable, or even writable, if the user’s `umask` setting allows. In typical usage on multi-user machines, the `umask` and/or the working directory’s permissions would be tight enough to prevent problems; but there may be people using `pg_upgrade` in scenarios where this oversight would permit disclosure of database passwords to unfriendly eyes. (CVE-2018-1053)

- Fix vacuuming of tuples that were updated while key-share locked (Andres Freund, Álvaro Herrera)

  In some cases `VACUUM` would fail to remove such tuples even though they are now dead, leading to assorted data corruption scenarios.

- Ensure that vacuum will always clean up the pending-insertions list of a GIN index (Masahiko Sawada)
This is necessary to ensure that dead index entries get removed. The old code got it backwards, allowing vacuum to skip the cleanup if some other process were running cleanup concurrently, thus risking invalid entries being left behind in the index.

- Fix inadequate buffer locking in some LSN fetches (Jacob Champion, Asim Praveen, Ashwin Agrawal)

These errors could result in misbehavior under concurrent load. The potential consequences have not been characterized fully.

- Fix incorrect query results from cases involving flattening of subqueries whose outputs are used in GROUPING SETS (Heikki Linnakangas)

- Avoid unnecessary failure in a query on an inheritance tree that occurs concurrently with some child table being removed from the tree by ALTER TABLE NO INHERIT (Tom Lane)

- Fix spurious deadlock failures when multiple sessions are running CREATE INDEX CONCURRENTLY (Jeff Janes)

- Fix failures when an inheritance tree contains foreign child tables (Etsuro Fujita)

  A mix of regular and foreign tables in an inheritance tree resulted in creation of incorrect plans for UPDATE and DELETE queries. This led to visible failures in some cases, notably when there are row-level triggers on a foreign child table.

- Repair failure with correlated sub-SELECT inside VALUES inside a LATERAL subquery (Tom Lane)

- Fix “could not devise a query plan for the given query” planner failure for some cases involving nested UNION ALL inside a lateral subquery (Tom Lane)

- Fix logical decoding to correctly clean up disk files for crashed transactions (Atsushi Torikoshi)

  Logical decoding may spill WAL records to disk for transactions generating many WAL records. Normally these files are cleaned up after the transaction’s commit or abort record arrives; but if no such record is ever seen, the removal code misbehaved.

- Fix walsender timeout failure and failure to respond to interrupts when processing a large transaction (Petr Jelinek)

- Fix has_sequence_privilege() to support WITH GRANT OPTION tests, as other privilege-testing functions do (Joe Conway)

- In databases using UTF8 encoding, ignore any XML declaration that asserts a different encoding (Pavel Stehule, Noah Misch)

  We always store XML strings in the database encoding, so allowing libxml to act on a declaration of another encoding gave wrong results. In encodings other than UTF8, we don’t promise to support non-ASCII XML data anyway, so retain the previous behavior for bug compatibility. This change affects only xpath() and related functions; other XML code paths already acted this way.

- Provide for forward compatibility with future minor protocol versions (Robert Haas, Badrul Chowdhury)

  Up to now, PostgreSQL servers simply rejected requests to use protocol versions newer than 3.0, so that there was no functional difference between the major and minor parts of the protocol version number. Allow clients to request versions 3.x without failing, sending back a message showing that the server only understands 3.0. This makes no difference at the moment, but back-patching this change should allow speedier introduction of future minor protocol upgrades.

- Cope with failure to start a parallel worker process (Amit Kapila, Robert Haas)

  Parallel query previously tended to hang indefinitely if a worker could not be started, as the result of fork() failure or other low-probability problems.
Appendix E. Release Notes

- Fix collection of `EXPLAIN` statistics from parallel workers (Amit Kapila, Thomas Munro)
- Avoid unsafe alignment assumptions when working with `__int128` (Tom Lane)
  Typically, compilers assume that `__int128` variables are aligned on 16-byte boundaries, but our memory allocation infrastructure isn’t prepared to guarantee that, and increasing the setting of `MAXALIGN` seems infeasible for multiple reasons. Adjust the code to allow use of `__int128` only when we can tell the compiler to assume lesser alignment. The only known symptom of this problem so far is crashes in some parallel aggregation queries.
- Prevent stack-overflow crashes when planning extremely deeply nested set operations (`UNION/INTERSECT/EXCEPT`) (Tom Lane)
- Fix null-pointer crashes for some types of LDAP URLs appearing in `pg_hba.conf` (Thomas Munro)
- Fix sample `INSTR()` functions in the PL/pgSQL documentation (Yugo Nagata, Tom Lane)
  These functions are stated to be Oracle® compatible, but they weren’t exactly. In particular, there was a discrepancy in the interpretation of a negative third parameter: Oracle thinks that a negative value indicates the last place where the target substring can begin, whereas our functions took it as the last place where the target can end. Also, Oracle throws an error for a zero or negative fourth parameter, whereas our functions returned zero.
  The sample code has been adjusted to match Oracle’s behavior more precisely. Users who have copied this code into their applications may wish to update their copies.
- Fix `pg_dump` to make ACL (permissions), comment, and security label entries reliably identifiable in archive output formats (Tom Lane)
  The “tag” portion of an ACL archive entry was usually just the name of the associated object. Make it start with the object type instead, bringing ACLs into line with the convention already used for comment and security label archive entries. Also, fix the comment and security label entries for the whole database, if present, to make their tags start with `DATABASE` so that they also follow this convention. This prevents false matches in code that tries to identify large-object-related entries by seeing if the tag starts with `LARGE OBJECT`. That could have resulted in misclassifying entries as data rather than schema, with undesirable results in a schema-only or data-only dump.
  Note that this change has user-visible results in the output of `pg_restore --list`.
- Rename `pg_rewind`’s `copy_file_range` function to avoid conflict with new Linux system call of that name (Andres Freund)
  This change prevents build failures with newer glibc versions.
- In `ecpg`, detect indicator arrays that do not have the correct length and report an error (David Rader)
- Change the behavior of `contrib/cube’s cube ~> int` operator to make it compatible with KNN search (Alexander Korotkov)
  The meaning of the second argument (the dimension selector) has been changed to make it predictable which value is selected even when dealing with cubes of varying dimensionalities.
  This is an incompatible change, but since the point of the operator was to be used in KNN searches, it seems rather useless as-is. After installing this update, any expression indexes or materialized views using this operator will need to be reindexed/refreshed.
- Avoid triggering a libc assertion in `contrib/hstore`, due to use of `memcpy()` with equal source and destination pointers (Tomas Vondra)
- Fix incorrect display of tuples’ null bitmaps in `contrib/pageinspect` (Maksim Milyutin)
• In contrib/postgres_fdw, avoid “outer pathkeys do not match mergeclauses” planner error when constructing a plan involving a remote join (Robert Haas)

• Provide modern examples of how to auto-start Postgres on macOS (Tom Lane)
  The scripts in contrib/start-scripts/osx use infrastructure that’s been deprecated for over a decade, and which no longer works at all in macOS releases of the last couple of years. Add a new subdirectory contrib/start-scripts/macos containing scripts that use the newer launchd infrastructure.

• Fix incorrect selection of configuration-specific libraries for OpenSSL on Windows (Andrew Dunstan)

• Support linking to MinGW-built versions of libperl (Noah Misch)
  This allows building PL/Perl with some common Perl distributions for Windows.

• Fix MSVC build to test whether 32-bit libperl needs -D_USE_32BIT_TIME_T (Noah Misch)
  Available Perl distributions are inconsistent about what they expect, and lack any reliable means of reporting it, so resort to a build-time test on what the library being used actually does.

• On Windows, install the crash dump handler earlier in postmaster startup (Takayuki Tsunakawa)
  This may allow collection of a core dump for some early-startup failures that did not produce a dump before.

• On Windows, avoid encoding-conversion-related crashes when emitting messages very early in postmaster startup (Takayuki Tsunakawa)

• Use our existing Motorola 68K spinlock code on OpenBSD as well as NetBSD (David Carlier)

• Add support for spinlocks on Motorola 88K (David Carlier)

• Update time zone data files to tzdata release 2018c for DST law changes in Brazil, Sao Tome and Principe, plus historical corrections for Bolivia, Japan, and South Sudan. The US/Pacific-New zone has been removed (it was only an alias for America/Los_Angeles anyway).

E.8. Release 9.6.6

Release date: 2017-11-09

This release contains a variety of fixes from 9.6.5. For information about new features in the 9.6 major release, see Section E.14.

E.8.1. Migration to Version 9.6.6

A dump/restore is not required for those running 9.6.X.
However, if you use BRIN indexes, see the fourth changelog entry below.
Also, if you are upgrading from a version earlier than 9.6.4, see Section E.10.
E.8.2. Changes

- Ensure that INSERT ... ON CONFLICT DO UPDATE checks table permissions and RLS policies in all cases (Dean Rasheed)
  
The update path of INSERT ... ON CONFLICT DO UPDATE requires SELECT permission on the columns of the arbiter index, but it failed to check for that in the case of an arbiter specified by constraint name. In addition, for a table with row level security enabled, it failed to check updated rows against the table’s SELECT policies (regardless of how the arbiter index was specified). (CVE-2017-15099)

- Fix crash due to rowtype mismatch in jsonb_populate_recordset() (Michael Paquier, Tom Lane)
  
  These functions used the result rowtype specified in the FROM ... AS clause without checking that it matched the actual rowtype of the supplied tuple value. If it didn’t, that would usually result in a crash, though disclosure of server memory contents seems possible as well. (CVE-2017-15098)

- Fix sample server-start scripts to become $PGUSER before opening $PGLOG (Noah Misch)
  
  Previously, the postmaster log file was opened while still running as root. The database owner could therefore mount an attack against another system user by making $PGLOG be a symbolic link to some other file, which would then become corrupted by appending log messages.

  By default, these scripts are not installed anywhere. Users who have made use of them will need to manually recopy them, or apply the same changes to their modified versions. If the existing $PGLOG file is root-owned, it will need to be removed or renamed out of the way before restarting the server with the corrected script. (CVE-2017-12172)

- Fix BRIN index summarization to handle concurrent table extension correctly (Álvaro Herrera)
  
  Previously, a race condition allowed some table rows to be omitted from the index. It may be necessary to reindex existing BRIN indexes to recover from past occurrences of this problem.

- Fix possible failures during concurrent updates of a BRIN index (Tom Lane)
  
  These race conditions could result in errors like “invalid index offnum” or “inconsistent range map”.

- Fix crash when logical decoding is invoked from a SPI-using function, in particular any function written in a PL language (Tom Lane)

- Fix incorrect query results when multiple GROUPING SETS columns contain the same simple variable (Tom Lane)

- Fix incorrect parallelization decisions for nested queries (Amit Kapila, Kuntal Ghosh)

- Fix parallel query handling to not fail when a recently-used role is dropped (Amit Kapila)

- Fix json_build_array(), json_build_object(), and their jsonb equivalents to handle explicit VARIADIC arguments correctly (Michael Paquier)

- Properly reject attempts to convert infinite float values to type numeric (Tom Lane, KaiGai Kohei)

  Previously the behavior was platform-dependent.

- Fix corner-case crashes when columns have been added to the end of a view (Tom Lane)

- Record proper dependencies when a view or rule contains FieldSelect or FieldStore expression nodes (Tom Lane)
Appendix E. Release Notes

Lack of these dependencies could allow a column or data type `DROP` to go through when it ought to fail, thereby causing later uses of the view or rule to get errors. This patch does not do anything to protect existing views/rules, only ones created in the future.

- Correctly detect hashability of range data types (Tom Lane)
  The planner mistakenly assumed that any range type could be hashed for use in hash joins or hash aggregation, but actually it must check whether the range’s subtype has hash support. This does not affect any of the built-in range types, since they’re all hashable anyway.

- Correctly ignore `RelabelType` expression nodes when determining relation distinctness (David Rowley)
  This allows the intended optimization to occur when a subquery has a result column of type `varchar`.

- Prevent sharing transition states between ordered-set aggregates (David Rowley)
  This causes a crash with the built-in ordered-set aggregates, and probably with user-written ones as well. v11 and later will include provisions for dealing with such cases safely, but in released branches, just disable the optimization.

- Prevent `idle_in_transaction_session_timeout` from being ignored when a `statement_timeout` occurred earlier (Lukas Fittl)

- Fix low-probability loss of NOTIFY messages due to XID wraparound (Marko Tiikkaja, Tom Lane)
  If a session executed no queries, but merely listened for notifications, for more than 2 billion transactions, it started to miss some notifications from concurrently-committing transactions.

- Avoid SIGBUS crash on Linux when a DSM memory request exceeds the space available in tmpfs (Thomas Munro)

- Reduce the frequency of data flush requests during bulk file copies to avoid performance problems on macOS, particularly with its new APFS file system (Tom Lane)

- Prevent low-probability crash in processing of nested trigger firings (Tom Lane)

- Allow `COPY`’s `FREEZE` option to work when the transaction isolation level is `REPEATABLE READ` or higher (Noah Misch)
  This case was unintentionally broken by a previous bug fix.

- Correctly restore the umask setting when file creation fails in `COPY` or `lo_export()` (Peter Eisentrut)

- Give a better error message for duplicate column names in `ANALYZE` (Nathan Bossart)

- Add missing cases in `GetCommandLogLevel()`, preventing errors when certain SQL commands are used while `log_statement` is set to `ddl` (Michael Paquier)

- Fix mis-parsing of the last line in a non-newline-terminated `pg_hba.conf` file (Tom Lane)

- Fix `AggGetAggref()` to return the correct `Aggref` nodes to aggregate final functions whose transition calculations have been merged (Tom Lane)

- Fix `pg_dump` to ensure that it emits `GRANT` commands in a valid order (Stephen Frost)
  This is particularly helpful on Windows.

- Fix `libpq` to not require user’s home directory to exist (Tom Lane)
In v10, failure to find the home directory while trying to read ~/.pgpass was treated as a hard error, but it should just cause that file to not be found. Both v10 and previous release branches made the same mistake when reading ~/.pg_service.conf, though this was less obvious since that file is not sought unless a service name is specified.

• Fix libpq to guard against integer overflow in the row count of a PGresult (Michael Paquier)
• Fix ecpg’s handling of out-of-scope cursor declarations with pointer or array variables (Michael Meskes)
• In ecpglib, correctly handle backslashes in string literals depending on whether standard_conforming_strings is set (Tsunakawa Takayuki)
• Make ecpglib’s Informix-compatibility mode ignore fractional digits in integer input strings, as expected (Gao Zengqi, Michael Meskes)
• Fix ecpg’s regression tests to work reliably on Windows (Christian Ullrich, Michael Meskes)
• Fix missing temp-install prerequisites for check-like Make targets (Noah Misch)
  Some non-default test procedures that are meant to work like make check failed to ensure that the temporary installation was up to date.
• Sync our copy of the timezone library with IANA release tzcode2017c (Tom Lane)
  This fixes various issues; the only one likely to be user-visible is that the default DST rules for a POSIX-style zone name, if no posixrules file exists in the timezone data directory, now match current US law rather than what it was a dozen years ago.
• Update time zone data files to tzdata release 2017c for DST law changes in Fiji, Namibia, Northern Cyprus, Sudan, Tonga, and Turks & Caicos Islands, plus historical corrections for Alaska, Apia, Burma, Calcutta, Detroit, Ireland, Namibia, and Pago Pago.

E.9. Release 9.6.5

Release date: 2017-08-31

This release contains a small number of fixes from 9.6.4. For information about new features in the 9.6 major release, see Section E.14.

E.9.1. Migration to Version 9.6.5

A dump/restore is not required for those running 9.6.X.

However, if you are upgrading from a version earlier than 9.6.4, see Section E.10.

E.9.2. Changes

• Show foreign tables in information_schema.table_privileges view (Peter Eisentraut)
  All other relevant information_schema views include foreign tables, but this one ignored them.
  Since this view definition is installed by initdb, merely upgrading will not fix the problem. If you need to fix this in an existing installation, you can, as a superuser, do this in psql:
  SET search_path TO information_schema;
CREATE OR REPLACE VIEW table_privileges AS
SELECT CAST(u_grantor.rolname AS sql_identifier) AS grantor,
    CAST(grantee.rolname AS sql_identifier) AS grantee,
    CAST(current_database() AS sql_identifier) AS table_catalog,
    CAST(nc.nspname AS sql_identifier) AS table_schema,
    CAST(c.relname AS sql_identifier) AS table_name,
    CAST(c.prtype AS character_data) AS privilege_type,
    CAST(
    CASE WHEN
        -- object owner always has grant options
        pg_has_role(grantee.oid, c.relowner, 'USAGE')
        OR c.grantable
    THEN 'YES' ELSE 'NO' END AS yes_or_no) AS is_grantable,
    CAST(CASE WHEN c.prtype = 'SELECT' THEN 'YES' ELSE 'NO' END AS yes_or_no) AS with_hierarchy
FROM (SELECT oid, relname, relnamespace, relkind, relowner, (aclexplode(coalesce(relacl, acldefault('r', relowner)))).* FROM pg_class)
    AS c (oid, relname, relnamespace, relkind, relowner, grantor, grantee, prtype, grantable), pg_namespace nc,
    pg_authid u_grantor,
    (SELECT oid, rolname FROM pg_authid
    UNION ALL
    SELECT 0::oid, 'PUBLIC') AS grantee (oid, rolname)
WHERE c.relnamespace = nc.oid
    AND c.relkind IN ('r', 'v', 'f')
    AND c.grantee = grantee.oid
    AND c.grantor = u_grantor.oid
    AND c.prtype IN ('INSERT', 'SELECT', 'UPDATE', 'DELETE', 'TRUNCATE', 'REFERENCES', 'TRIGGER')
    AND (pg_has_role(u_grantor.oid, 'USAGE')
        OR pg_has_role(grantee.oid, 'USAGE')
        OR grantee.rolname = 'PUBLIC');

This must be repeated in each database to be fixed, including template0.

- Clean up handling of a fatal exit (e.g., due to receipt of SIGTERM) that occurs while trying to execute a ROLLBACK of a failed transaction (Tom Lane)
  This situation could result in an assertion failure. In production builds, the exit would still occur, but it would log an unexpected message about “cannot drop active portal”.
- Remove assertion that could trigger during a fatal exit (Tom Lane)
- Correctly identify columns that are of a range type or domain type over a composite type or domain type being searched for (Tom Lane)
  Certain ALTER commands that change the definition of a composite type or domain type are supposed to fail if there are any stored values of that type in the database, because they lack the infrastructure needed to update or check such values. Previously, these checks could miss relevant values that are wrapped inside range types or sub-domains, possibly allowing the database to become inconsistent.
- Prevent crash when passing fixed-length pass-by-reference data types to parallel worker processes (Tom Lane)
- Fix crash in pg_restore when using parallel mode and using a list file to select a subset of items to restore (Fabrizio de Royes Mello)
- Change ecpg’s parser to allow RETURNING clauses without attached C variables (Michael Meskes)
This allows ecpg programs to contain SQL constructs that use `RETURNING` internally (for example, inside a CTE) rather than using it to define values to be returned to the client.

- Change ecpg’s parser to recognize backslash continuation of C preprocessor command lines (Michael Meskes)
- Improve selection of compiler flags for PL/Perl on Windows (Tom Lane)
  This fix avoids possible crashes of PL/Perl due to inconsistent assumptions about the width of `time_t` values. A side-effect that may be visible to extension developers is that `_USE_32BIT_TIME_T` is no longer defined globally in PostgreSQL Windows builds. This is not expected to cause problems, because type `time_t` is not used in any PostgreSQL API definitions.
- Fix `make check` to behave correctly when invoked via a non-GNU make program (Thomas Munro)

E.10. Release 9.6.4

Release date: 2017-08-10

This release contains a variety of fixes from 9.6.3. For information about new features in the 9.6 major release, see Section E.14.

E.10.1. Migration to Version 9.6.4

A dump/restore is not required for those running 9.6.X.

However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.

Also, if you are upgrading from a version earlier than 9.6.3, see Section E.11.

E.10.2. Changes

- Further restrict visibility of `pg_user_mappings.umoptions`, to protect passwords stored as user mapping options (Noah Misch)
  The fix for CVE-2017-7486 was incorrect: it allowed a user to see the options in her own user mapping, even if she did not have `USAGE` permission on the associated foreign server. Such options might include a password that had been provided by the server owner rather than the user herself. Since `information_schema.user_mapping_options` does not show the options in such cases, `pg_user_mappings` should not either. (CVE-2017-7547)
  By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, you will need to do the following:

  1. Restart the postmaster after adding `allow_system_table_mods = true` to `postgresql.conf`. (In versions supporting `ALTER SYSTEM`, you can use that to make the configuration change, but you’ll still need a restart.)
  2. In each database of the cluster, run the following commands as superuser:

     ```sql
     SET search_path = pg_catalog;
     ```
CREATE OR REPLACE VIEW pg_user_mappings AS
SELECT
  U.oid AS umid,
  S.oid AS srvid,
  S.srvname AS srvname,
  U.umuser AS umuser,
  CASE WHEN U.umuser = 0 THEN
    'public'
  ELSE
    A.rolname
  END AS usename,
  CASE WHEN (U.umuser <> 0 AND A.rolname = current_user
    AND (pg_has_role(S.srvowner, 'USAGE')
      OR has_server_privilege(S.oid, 'USAGE')))
    OR (U.umuser = 0 AND pg_has_role(S.srvowner, 'USAGE'))
    OR (SELECT rolsuper FROM pg_authid WHERE rolname = current_user
      THEN U.umoptions
  ELSE NULL END AS umoptions
FROM pg_user_mapping U
LEFT JOIN pg_authid A ON (A.oid = U.umuser) JOIN
pg_foreign_server S ON (U.umserver = S.oid);

3. Do not forget to include the template0 and template1 databases, or the vulnerability will still exist in databases you create later. To fix template0, you’ll need to temporarily make it accept connections. In PostgreSQL 9.5 and later, you can use
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS true;
and then after fixing template0, undo that with
ALTER DATABASE template0 WITH ALLOW_CONNECTIONS false;
In prior versions, instead use
UPDATE pg_database SET datallowconn = true WHERE datname = 'template0';
UPDATE pg_database SET datallowconn = false WHERE datname = 'template0';

4. Finally, remove the allow_system_table_mods configuration setting, and again restart the postmaster.

- Disallow empty passwords in all password-based authentication methods (Heikki Linnakangas)
  libpq ignores empty password specifications, and does not transmit them to the server. So, if a user’s password has been set to the empty string, it’s impossible to log in with that password via psql or other libpq-based clients. An administrator might therefore believe that setting the password to empty is equivalent to disabling password login. However, with a modified or non-libpq-based client, logging in could be possible, depending on which authentication method is configured. In particular the most common method, md5, accepted empty passwords. Change the server to reject empty passwords in all cases. (CVE-2017-7546)

- Make lo_put() check for UPDATE privilege on the target large object (Tom Lane, Michael Paquier)
  lo_put() should surely require the same permissions as lowrite(), but the check was missing, allowing any user to change the data in a large object. (CVE-2017-7548)

- Correct the documentation about the process for upgrading standby servers with pg_upgrade (Bruce Momjian)
  The previous documentation instructed users to start/stop the primary server after running pg_upgrade but before syncing the standby servers. This sequence is unsafe.
• Fix concurrent locking of tuple update chains (Álvaro Herrera)
  If several sessions concurrently lock a tuple update chain with nonconflicting lock modes using
  an old snapshot, and they all succeed, it was possible for some of them to nonetheless fail (and
  conclude there is no live tuple version) due to a race condition. This had consequences such as
  foreign-key checks failing to see a tuple that definitely exists but is being updated concurrently.
• Fix potential data corruption when freezing a tuple whose XMAX is a multixact with exactly one
  still-interesting member (Teodor Sigaev)
• Avoid integer overflow and ensuing crash when sorting more than one billion tuples in-memory
  (Sergey Koposov)
• On Windows, retry process creation if we fail to reserve the address range for our shared memory
  in the new process (Tom Lane, Amit Kapila)
  This is expected to fix infrequent child-process-launch failures that are probably due to interference
  from antivirus products.
• Fix low-probability corruption of shared predicate-lock hash table in Windows builds (Thomas
  Munro, Tom Lane)
• Avoid logging clean closure of an SSL connection as though it were a connection reset (Michael
  Paquier)
• Prevent sending SSL session tickets to clients (Tom Lane)
  This fix prevents reconnection failures with ticket-aware client-side SSL code.
• Fix code for setting tcp_keepalives_idle on Solaris (Tom Lane)
• Fix statistics collector to honor inquiry messages issued just after a postmaster shutdown and im-
  mediate restart (Tom Lane)
  Statistics inquiries issued within half a second of the previous postmaster shutdown were effectively
  ignored.
• Ensure that the statistics collector’s receive buffer size is at least 100KB (Tom Lane)
  This reduces the risk of dropped statistics data on older platforms whose default receive buffer size
  is less than that.
• Fix possible creation of an invalid WAL segment when a standby is promoted just after it processes
  an XLOG_SWITCH WAL record (Andres Freund)
• Fix walsender to exit promptly when client requests shutdown (Tom Lane)
• Fix SIGHUP and SIGUSR1 handling in walsender processes (Petr Jelinek, Andres Freund)
• Prevent walsender-triggered panics during shutdown checkpoints (Andres Freund, Michael
  Paquier)
• Fix unnecessarily slow restarts of walreceiver processes due to race condition in postmaster (Tom
  Lane)
• Fix leakage of small subtransactions spilled to disk during logical decoding (Andres Freund)
  This resulted in temporary files consuming excessive disk space.
• Reduce the work needed to build snapshots during creation of logical-decoding slots (Andres Fre-
  und, Petr Jelinek)
  The previous algorithm was infeasibly expensive on a server with a lot of open transactions.
• Fix race condition that could indefinitely delay creation of logical-decoding slots (Andres Freund,
  Petr Jelinek)
• Reduce overhead in processing syscache invalidation events (Tom Lane)
  This is particularly helpful for logical decoding, which triggers frequent cache invalidation.

• Remove incorrect heuristic used in some cases to estimate join selectivity based on the presence of
  foreign-key constraints (David Rowley)
  In some cases where a multi-column foreign key constraint existed but did not exactly match a
  query’s join structure, the planner used an estimation heuristic that turns out not to work well at all.
  Revert such cases to the way they were estimated before 9.6.

• Fix cases where an INSERT or UPDATE assigns to more than one element of a column that is of
  domain-over-array type (Tom Lane)

• Allow window functions to be used in sub-SELECTs that are within the arguments of an aggregate
  function (Tom Lane)

• Ensure that a view’s CHECK OPTIONS clause is enforced properly when the underlying table is a
  foreign table (Etsuro Fujita)
  Previously, the update might get pushed entirely to the foreign server, but the need to verify the
  view conditions was missed if so.

• Move autogenerated array types out of the way during ALTER ... RENAME (Vik Fearing)
  Previously, we would rename a conflicting autogenerated array type out of the way during CREATE;
  this fix extends that behavior to renaming operations.

• Fix dangling pointer in ALTER TABLE when there is a comment on a constraint belonging to the
  table (David Rowley)
  Re-applying the comment to the reconstructed constraint could fail with a weird error message, or
  even crash.

• Ensure that ALTER USER ... SET accepts all the syntax variants that ALTER ROLE ... SET
  does (Peter Eisentraut)

• Allow a foreign table’s CHECK constraints to be initially NOT VALID (Amit Langote)
  CREATE TABLE silently drops NOT VALID specifiers for CHECK constraints, reasoning that the
  table must be empty so the constraint can be validated immediately. But this is wrong for CREATE
  FOREIGN TABLE, where there’s no reason to suppose that the underlying table is empty, and even
  if it is it’s no business of ours to decide that the constraint can be treated as valid going forward.
  Skip this “optimization” for foreign tables.

• Properly update dependency info when changing a datatype I/O function’s argument or return type
  from opaque to the correct type (Heikki Linnakangas)

• Allow parallelism in the query plan when COPY copies from a query’s result (Andres Freund)

• Reduce memory usage when ANALYZE processes a tsvector column (Heikki Linnakangas)

• Fix unnecessary precision loss and sloppy rounding when multiplying or dividing money values by
  integers or floats (Tom Lane)

• Tighten checks for whitespace in functions that parse identifiers, such as regprocedurein() (Tom Lane)
  Depending on the prevailing locale, these functions could misinterpret fragments of multibyte char-
  acters as whitespace.
Appendix E. Release Notes

• Use relevant #define symbols from Perl while compiling PL/Perl (Ashutosh Sharma, Tom Lane)
  This avoids portability problems, typically manifesting as a “handshake” mismatch during library load, when working with recent Perl versions.

• In libpq, reset GSS/SASL and SSPI authentication state properly after a failed connection attempt (Michael Paquier)
  Failure to do this meant that when falling back from SSL to non-SSL connections, a GSS/SASL failure in the SSL attempt would always cause the non-SSL attempt to fail. SSPI did not fail, but it leaked memory.

• In psql, fix failure when COPY FROM STDIN is ended with a keyboard EOF signal and then another COPY FROM STDIN is attempted (Thomas Munro)
  This misbehavior was observed on BSD-derived platforms (including macOS), but not on most others.

• Fix pg_dump and pg_restore to emit REFRESH MATERIALIZED VIEW commands last (Tom Lane)
  This prevents errors during dump/restore when a materialized view refers to tables owned by a different user.

• Improve pg_dump/pg_restore’s reporting of error conditions originating in zlib (Vladimir Kunschikov, Álvaro Herrera)

• Fix pg_dump with the --clean option to drop event triggers as expected (Tom Lane)
  It also now correctly assigns ownership of event triggers; before, they were restored as being owned by the superuser running the restore script.

• Fix pg_dump with the --clean option to not fail when the public schema doesn’t exist (Stephen Frost)

• Fix pg_dump to not emit invalid SQL for an empty operator class (Daniel Gustafsson)

• Fix pg_dump output to stdout on Windows (Kuntal Ghosh)
  A compressed plain-text dump written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_get_ruledef() to print correct output for the ON SELECT rule of a view whose columns have been renamed (Tom Lane)
  In some corner cases, pg_dump relies on pg_get_ruledef() to dump views, so that this error could result in dump/reload failures.

• Fix dumping of outer joins with empty constraints, such as the result of a NATURAL LEFT JOIN with no common columns (Tom Lane)

• Fix dumping of function expressions in the FROM clause in cases where the expression does not deparse into something that looks like a function call (Tom Lane)

• Fix pg_basebackup output to stdout on Windows (Haribabu Kommi)
  A backup written to stdout would contain corrupt data due to failure to put the file descriptor into binary mode.

• Fix pg_rewind to correctly handle files exceeding 2GB (Kuntal Ghosh, Michael Paquier)
  Ordinarily such files won’t appear in PostgreSQL data directories, but they could be present in some cases.

• Fix pg_upgrade to ensure that the ending WAL record does not have wal_level = minimum (Bruce Momjian)
This condition could prevent upgraded standby servers from reconnecting.

- Fix pg_xlogdump’s computation of WAL record length (Andres Freund)
- In postgres_fdw, re-establish connections to remote servers after ALTER SERVER or ALTER USER MAPPING commands (Kyotaro Horiguchi)
  This ensures that option changes affecting connection parameters will be applied promptly.
- In postgres_fdw, allow cancellation of remote transaction control commands (Robert Haas, Rafia Sabih)
  This change allows us to quickly escape a wait for an unresponsive remote server in many more cases than previously.
- Increase MAX_SYSCACHE_CALLBACKS to provide more room for extensions (Tom Lane)
- Always use -fPIC, not -fpic, when building shared libraries with gcc (Tom Lane)
  This supports larger extension libraries on platforms where it makes a difference.
- In MSVC builds, handle the case where the openssl library is not within a VC subdirectory (Andrew Dunstan)
- In MSVC builds, add proper include path for libxml2 header files (Andrew Dunstan)
  This fixes a former need to move things around in standard Windows installations of libxml2.
- In MSVC builds, recognize a Tcl library that is named tcl86.lib (Noah Misch)
- In MSVC builds, honor PROVE_FLAGS settings on vcregress.pl’s command line (Andrew Dunstan)

E.11. Release 9.6.3

Release date: 2017-05-11
This release contains a variety of fixes from 9.6.2. For information about new features in the 9.6 major release, see Section E.14.

E.11.1. Migration to Version 9.6.3
A dump/restore is not required for those running 9.6.X.
However, if you use foreign data servers that make use of user passwords for authentication, see the first changelog entry below.
Also, if you are using third-party replication tools that depend on “logical decoding”, see the fourth changelog entry below.
Also, if you are upgrading from a version earlier than 9.6.2, see Section E.12.

E.11.2. Changes

- Restrict visibility of pg_user_mappings.umoptions, to protect passwords stored as user mapping options (Michael Paquier, Feike Steenbergen)
The previous coding allowed the owner of a foreign server object, or anyone he has granted server USAGE permission to, to see the options for all user mappings associated with that server. This might well include passwords for other users. Adjust the view definition to match the behavior of information_schema.user_mapping_options, namely that these options are visible to the user being mapped, or if the mapping is for PUBLIC and the current user is the server owner, or if the current user is a superuser. (CVE-2017-7486)

By itself, this patch will only fix the behavior in newly initdb’d databases. If you wish to apply this change in an existing database, follow the corrected procedure shown in the changelog entry for CVE-2017-7547, in Section E.10.

• Prevent exposure of statistical information via leaky operators (Peter Eisentraut)
  Some selectivity estimation functions in the planner will apply user-defined operators to values obtained from pg_statistic, such as most common values and histogram entries. This occurs before table permissions are checked, so a nefarious user could exploit the behavior to obtain these values for table columns he does not have permission to read. To fix, fall back to a default estimate if the operator’s implementation function is not certified leak-proof and the calling user does not have permission to read the table column whose statistics are needed. At least one of these criteria is satisfied in most cases in practice. (CVE-2017-7484)

• Restore libpq’s recognition of the PGREQUIRESSL environment variable (Daniel Gustafsson)
  Processing of this environment variable was unintentionally dropped in PostgreSQL 9.3, but its documentation remained. This creates a security hazard, since users might be relying on the environment variable to force SSL-encrypted connections, but that would no longer be guaranteed. Restore handling of the variable, but give it lower priority than PGSSLMODE, to avoid breaking configurations that work correctly with post-9.3 code. (CVE-2017-7485)

• Fix possibly-invalid initial snapshot during logical decoding (Petr Jelinek, Andres Freund)
  The initial snapshot created for a logical decoding replication slot was potentially incorrect. This could cause third-party tools that use logical decoding to copy incomplete/inconsistent initial data. This was more likely to happen if the source server was busy at the time of slot creation, or if another logical slot already existed.

  If you are using a replication tool that depends on logical decoding, and it should have copied a nonempty data set at the start of replication, it is advisable to recreate the replica after installing this update, or to verify its contents against the source server.

• Fix possible corruption of “init forks” of unlogged indexes (Robert Haas, Michael Paquier)
  This could result in an unlogged index being set to an invalid state after a crash and restart. Such a problem would persist until the index was dropped and rebuilt.

• Fix incorrect reconstruction of pg_subtrans entries when a standby server replays a prepared but uncommitted two-phase transaction (Tom Lane)
  In most cases this turned out to have no visible ill effects, but in corner cases it could result in circular references in pg_subtrans, potentially causing infinite loops in queries that examine rows modified by the two-phase transaction.

• Avoid possible crash in walsender due to failure to initialize a string buffer (Stas Kelvich, Fujii Masao)

• Fix possible crash when rescanning a nearest-neighbor index-only scan on a GiST index (Tom Lane)

• Prevent delays in postmaster’s launching of multiple parallel worker processes (Tom Lane)
Appendix E. Release Notes

There could be a significant delay (up to tens of seconds) before satisfying a query’s request for more than one worker process, or when multiple queries requested workers simultaneously. On most platforms this required unlucky timing, but on some it was the typical case.

- Fix postmaster’s handling of fork() failure for a background worker process (Tom Lane)
  Previously, the postmaster updated portions of its state as though the process had been launched successfully, resulting in subsequent confusion.
- Fix possible “no relation entry for relid 0” error when planning nested set operations (Tom Lane)
- Fix assorted minor issues in planning of parallel queries (Robert Haas)
- Avoid applying “physical targetlist” optimization to custom scans (Dmitry Ivanov, Tom Lane)
  This optimization supposed that retrieving all columns of a tuple is inexpensive, which is true for ordinary Postgres tuples; but it might not be the case for a custom scan provider.
- Use the correct sub-expression when applying a FOR ALL row-level-security policy (Stephen Frost)
  In some cases the WITH CHECK restriction would be applied when the USING restriction is more appropriate.
- Ensure parsing of queries in extension scripts sees the results of immediately-preceding DDL (Julien Rouhaud, Tom Lane)
  Due to lack of a cache flush step between commands in an extension script file, non-utility queries might not see the effects of an immediately preceding catalog change, such as ALTER TABLE ... RENAME.
- Skip tablespace privilege checks when ALTER TABLE ... ALTER COLUMN TYPE rebuilds an existing index (Noah Misch)
  The command failed if the calling user did not currently have CREATE privilege for the tablespace containing the index. That behavior seems unhelpful, so skip the check, allowing the index to be rebuilt where it is.
- Fix ALTER TABLE ... VALIDATE CONSTRAINT to not recurse to child tables when the constraint is marked NO INHERIT (Amit Langote)
  This fix prevents unwanted “constraint does not exist” failures when no matching constraint is present in the child tables.
- Avoid dangling pointer in COPY ... TO when row-level security is active for the source table (Tom Lane)
  Usually this had no ill effects, but sometimes it would cause unexpected errors or crashes.
- Avoid accessing an already-closed relcache entry in CLUSTER and VACUUM FULL (Tom Lane)
  With some bad luck, this could lead to indexes on the target relation getting rebuilt with the wrong persistence setting.
- Fix VACUUM to account properly for pages that could not be scanned due to conflicting page pins (Andrew Gierth)
  This tended to lead to underestimation of the number of tuples in the table. In the worst case of a small heavily-contended table, VACUUM could incorrectly report that the table contained no tuples, leading to very bad planning choices.
- Ensure that bulk-tuple-transfer loops within a hash join are interruptible by query cancel requests (Tom Lane, Thomas Munro)
- Fix incorrect support for certain box operators in SP-GiST (Nikita Glukhov)
  SP-GiST index scans using the operators &< &> &<| and |&> would yield incorrect answers.
Appendix E. Release Notes

• Fix integer-overflow problems in interval comparison (Kyotaro Horiguchi, Tom Lane)
  The comparison operators for type interval could yield wrong answers for intervals larger than about 296000 years. Indexes on columns containing such large values should be reindexed, since they may be corrupt.

• Fix cursor_to_xml() to produce valid output with tableforest = false (Thomas Munro, Peter Eisentraut)
  Previously it failed to produce a wrapping <table> element.

• Fix roundoff problems in float8_timestamptz() and make_interval() (Tom Lane)
  These functions truncated, rather than rounded, when converting a floating-point value to integer microseconds; that could cause unexpectedly off-by-one results.

• Fix pg_get_object_address() to handle members of operator families correctly (Álvaro Herrera)

• Fix cancelling of pg_stop_backup() when attempting to stop a non-exclusive backup (Michael Paquier, David Steele)
  If pg_stop_backup() was cancelled while waiting for a non-exclusive backup to end, related state was left inconsistent; a new exclusive backup could not be started, and there were other minor problems.

• Improve performance of pg_timezone_names view (Tom Lane, David Rowley)

• Reduce memory management overhead for contexts containing many large blocks (Tom Lane)

• Fix sloppy handling of corner-case errors from lseek() and close() (Tom Lane)
  Neither of these system calls are likely to fail in typical situations, but if they did, fd.c could get quite confused.

• Fix incorrect check for whether postmaster is running as a Windows service (Michael Paquier)
  This could result in attempting to write to the event log when that isn’t accessible, so that no logging happens at all.

• Fix ecpg to support COMMIT PREPARED and ROLLBACK PREPARED (Masahiko Sawada)

• Fix a double-free error when processing dollar-quoted string literals in ecpg (Michael Meskes)

• Fix pgbench to handle the combination of --connect and --rate options correctly (Fabien Coelho)

• Fix pgbench to honor the long-form option spelling --builtin, as per its documentation (Tom Lane)

• Fix pg_dump/pg_restore to correctly handle privileges for the public schema when using --clean option (Stephen Frost)
  Other schemas start out with no privileges granted, but public does not; this requires special-case treatment when it is dropped and restored due to the --clean option.

• In pg_dump, fix incorrect schema and owner marking for comments and security labels of some types of database objects (Giuseppe Broccolo, Tom Lane)
  In simple cases this caused no ill effects; but for example, a schema-selective restore might omit comments it should include, because they were not marked as belonging to the schema of their associated object.

• Fix typo in pg_dump’s query for initial privileges of a procedural language (Peter Eisentraut)
This resulted in pg_dump always believing that the language had no initial privileges. Since that’s true for most procedural languages, ill effects from this bug are probably rare.

- Avoid emitting an invalid list file in \texttt{pg\_restore -l} when SQL object names contain newlines (Tom Lane)
  
  Replace newlines by spaces, which is sufficient to make the output valid for \texttt{pg\_restore -L}’s purposes.

- Fix \texttt{pg\_upgrade} to transfer comments and security labels attached to “large objects” (blobs) (Stephen Frost)
  
  Previously, blobs were correctly transferred to the new database, but any comments or security labels attached to them were lost.

- Improve error handling in \texttt{contrib/adminpack\_pg\_file\_write()} function (Noah Misch)
  
  Notably, it failed to detect errors reported by \texttt{fclose()}.

- In \texttt{contrib/dblink}, avoid leaking the previous unnamed connection when establishing a new unnamed connection (Joe Conway)

- Fix \texttt{contrib/pg\_trgm}’s extraction of trigrams from regular expressions (Tom Lane)
  
  In some cases it would produce a broken data structure that could never match anything, leading to GIN or GiST indexscans that use a trigram index not finding any matches to the regular expression.

- In \texttt{contrib/postgres\_fdw}, allow join conditions that contain shippable extension-provided functions to be pushed to the remote server (David Rowley, Ashutosh Bapat)

- Support Tcl 8.6 in MSVC builds (Álvaro Herrera)

- Sync our copy of the timezone library with IANA release tzcode2017b (Tom Lane)
  
  This fixes a bug affecting some DST transitions in January 2038.

- Update time zone data files to tzdata release 2017b for DST law changes in Chile, Haiti, and Mongolia, plus historical corrections for Ecuador, Kazakhstan, Liberia, and Spain. Switch to numeric abbreviations for numerous time zones in South America, the Pacific and Indian oceans, and some Asian and Middle Eastern countries.

  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the \texttt{pg\_timezone\_names} view nor used for output.

- Use correct daylight-savings rules for POSIX-style time zone names in MSVC builds (David Rowley)

  The Microsoft MSVC build scripts neglected to install the \texttt{posixrules} file in the timezone directory tree. This resulted in the timezone code falling back to its built-in rule about what DST behavior to assume for a POSIX-style time zone name. For historical reasons that still corresponds to the DST rules the USA was using before 2007 (i.e., change on first Sunday in April and last Sunday in October). With this fix, a POSIX-style zone name will use the current and historical DST transition dates of the US/Eastern zone. If you don’t want that, remove the \texttt{posixrules} file, or replace it with a copy of some other zone file (see Section 8.5.3). Note that due to caching, you may need to restart the server to get such changes to take effect.
E.12. Release 9.6.2

**Release date:** 2017-02-09

This release contains a variety of fixes from 9.6.1. For information about new features in the 9.6 major release, see Section E.14.

### E.12.1. Migration to Version 9.6.2

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bug described in the first changelog entry below, then after updating you may need to take action to repair corrupted indexes.

Also, if you are upgrading from a version earlier than 9.6.1, see Section E.13.

### E.12.2. Changes

- **Fix a race condition that could cause indexes built with** `CREATE INDEX CONCURRENTLY` **to be corrupt** (Pavan Deolasee, Tom Lane)
  
  If `CREATE INDEX CONCURRENTLY` was used to build an index that depends on a column not previously indexed, then rows updated by transactions that ran concurrently with the `CREATE INDEX` command could have received incorrect index entries. If you suspect this may have happened, the most reliable solution is to rebuild affected indexes after installing this update.

- **Ensure that the special snapshot used for catalog scans is not invalidated by premature data pruning** (Tom Lane)
  
  Backends failed to account for this snapshot when advertising their oldest xmin, potentially allowing concurrent vacuuming operations to remove data that was still needed. This led to transient failures along the lines of “cache lookup failed for relation 1255”.

- **Fix incorrect WAL logging for BRIN indexes** (Kuntal Ghosh)
  
  The WAL record emitted for a BRIN “revmap” page when moving an index tuple to a different page was incorrect. Replay would make the related portion of the index useless, forcing it to be recomputed.

- **Unconditionally WAL-log creation of the “init fork” for an unlogged table** (Michael Paquier)
  
  Previously, this was skipped when `wal_level = minimal`, but actually it’s necessary even in that case to ensure that the unlogged table is properly reset to empty after a crash.

- **If the stats collector dies during hot standby, restart it** (Takayuki Tsunakawa)

- **Ensure that hot standby feedback works correctly when it’s enabled at standby server start** (Ants Aasma, Craig Ringer)

- **Check for interrupts while hot standby is waiting for a conflicting query** (Simon Riggs)

- **Avoid constantly respawning the autovacuum launcher in a corner case** (Amit Khandekar)
  
  This fix avoids problems when autovacuum is nominally off and there are some tables that require freezing, but all such tables are already being processed by autovacuum workers.

- **Disallow setting the** `num_sync` **field to zero in synchronous_standby_names** (Fujii Masao)
  
  The correct way to disable synchronous standby is to set the whole value to an empty string.
• Don’t count background worker processes against a user’s connection limit (David Rowley)

• Fix check for when an extension member object can be dropped (Tom Lane)
  Extension upgrade scripts should be able to drop member objects, but this was disallowed for serial-column sequences, and possibly other cases.

• Fix tracking of initial privileges for extension member objects so that it works correctly with ALTER EXTENSION ... ADD/DROP (Stephen Frost)
  An object’s current privileges at the time it is added to the extension will now be considered its default privileges; only later changes in its privileges will be dumped by subsequent pg_dump runs.

• Make sure ALTER TABLE preserves index tablespace assignments when rebuilding indexes (Tom Lane, Michael Paquier)
  Previously, non-default settings of default_tablespace could result in broken indexes.

• Fix incorrect updating of trigger function properties when changing a foreign-key constraint’s deferrability properties with ALTER TABLE ... ALTER CONSTRAINT (Tom Lane)
  This led to odd failures during subsequent exercise of the foreign key, as the triggers were fired at the wrong times.

• Prevent dropping a foreign-key constraint if there are pending trigger events for the referenced relation (Tom Lane)
  This avoids “could not find trigger NNN” or “relation NNN has no triggers” errors.

• Fix ALTER TABLE ... SET DATA TYPE ... USING when child table has different column ordering than the parent (Álvaro Herrera)
  Failure to adjust the column numbering in the USING expression led to errors, typically “attribute N has wrong type”.

• Fix processing of OID column when a table with OIDs is associated to a parent with OIDs via ALTER TABLE ... INHERIT (Amit Langote)
  The OID column should be treated the same as regular user columns in this case, but it wasn’t, leading to odd behavior in later inheritance changes.

• Ensure that CREATE TABLE ... LIKE ... WITH OIDS creates a table with OIDs, whether or not the LIKE-referenced table(s) have OIDs (Tom Lane)

• Fix CREATE OR REPLACE VIEW to update the view query before attempting to apply the new view options (Dean Rasheed)
  Previously the command would fail if the new options were inconsistent with the old view definition.

• Report correct object identity during ALTER TEXT SEARCH CONFIGURATION (Artur Zakirov)
  The wrong catalog OID was reported to extensions such as logical decoding.

• Fix commit timestamp mechanism to not fail when queried about the special XIDs FrozenTransactionId and BootstrapTransactionId (Craig Ringer)

• Fix incorrect use of view reloptions as regular table reloptions (Tom Lane)
  The symptom was spurious “ON CONFLICT is not supported on table ... used as a catalog table” errors when the target of INSERT ... ON CONFLICT is a view with cascade option.

• Fix incorrect “target lists can have at most N entries” complaint when using ON CONFLICT with wide tables (Tom Lane)
Appendix E. Release Notes

- Fix spurious “query provides a value for a dropped column” errors during `INSERT` or `UPDATE` on a table with a dropped column (Tom Lane)

- Prevent multicolumn expansion of `foo.*` in an `UPDATE` source expression (Tom Lane)
  This led to “UPDATE target count mismatch --- internal error”. Now the syntax is understood as a whole-row variable, as it would be in other contexts.

- Ensure that column typmods are determined accurately for multi-row `VALUES` constructs (Tom Lane)
  This fixes problems occurring when the first value in a column has a determinable typmod (e.g., length for a `varchar` value) but later values don’t share the same limit.

- Throw error for an unfinished Unicode surrogate pair at the end of a Unicode string (Tom Lane)
  Normally, a Unicode surrogate leading character must be followed by a Unicode surrogate trailing character, but the check for this was missed if the leading character was the last character in a Unicode string literal (`U&'...'`) or Unicode identifier (`U&"..."`).

- Fix execution of `DISTINCT` and ordered aggregates when multiple such aggregates are able to share the same transition state (Heikki Linnakangas)

- Fix implementation of phrase search operators in `tsquery` (Tom Lane)
  Remove incorrect, and inconsistently-applied, rewrite rules that tried to transform away AND/OR/NOT operators appearing below a PHRASE operator; instead upgrade the execution engine to handle such cases correctly. This fixes assorted strange behavior and possible crashes for text search queries containing such combinations. Also fix nested PHRASE operators to work sanely in combinations other than simple left-deep trees, correct the behavior when removing stopwords from a phrase search clause, and make sure that index searches behave consistently with simple sequential-scan application of such queries.

- Ensure that a purely negative text search query, such as `!foo`, matches empty `tsvector`s (Tom Dunstan)
  Such matches were found by GIN index searches, but not by sequential scans or GiST index searches.

- Prevent crash when `ts_rewrite()` replaces a non-top-level subtree with an empty query (Artur Zakirov)

- Fix performance problems in `ts_rewrite()` (Tom Lane)

- Fix `ts_rewrite()`’s handling of nested NOT operators (Tom Lane)

- Improve speed of user-defined aggregates that use `array_append()` as transition function (Tom Lane)

- Fix `array_fill()` to handle empty arrays properly (Tom Lane)

- Fix possible crash in `array_position()` or `array_positions()` when processing arrays of records (Junseok Yang)

- Fix one-byte buffer overrun in `quote_literal_cstr()` (Heikki Linnakangas)
  The overrun occurred only if the input consisted entirely of single quotes and/or backslashes.

- Prevent multiple calls of `pg_start_backup()` and `pg_stop_backup()` from running concurrently (Michael Paquier)
  This avoids an assertion failure, and possibly worse things, if someone tries to run these functions in parallel.

- Disable transform that attempted to remove no-op `AT TIME ZONE` conversions (Tom Lane)
Appendix E. Release Notes

This resulted in wrong answers when the simplified expression was used in an index condition.

• Avoid discarding interval-to-interval casts that aren’t really no-ops (Tom Lane)

In some cases, a cast that should result in zeroing out low-order interval fields was mistakenly deemed to be a no-op and discarded. An example is that casting from INTERVAL MONTH to INTERVAL YEAR failed to clear the months field.

• Fix crash if the number of workers available to a parallel query decreases during a rescan (Andreas Seltenreich)

• Fix bugs in transmitting GUC parameter values to parallel workers (Michael Paquier, Tom Lane)

• Allow statements prepared with PREPARE to be given parallel plans (Amit Kapila, Tobias Bussmann)

• Fix incorrect generation of parallel plans for semi-joins (Tom Lane)

• Fix planner’s cardinality estimates for parallel joins (Robert Haas)

Ensure that these estimates reflect the number of rows predicted to be seen by each worker, rather than the total.

• Fix planner to avoid trying to parallelize plan nodes containing initplans or subplans (Tom Lane, Amit Kapila)

• Ensure that cached plans are invalidated by changes in foreign-table options (Amit Langote, Etsuro Fujita, Ashutosh Bapat)

• Fix the plan generated for sorted partial aggregation with a constant GROUP BY clause (Tom Lane)

• Fix “could not find plan for CTE” planner error when dealing with a UNION ALL containing CTE references (Tom Lane)

• Fix mishandling of initplans when forcibly adding a Material node to a subplan (Tom Lane)

The typical consequence of this mistake was a “plan should not reference subplan’s variable” error.

• Fix foreign-key-based join selectivity estimation for semi-joins and anti-joins, as well as inheritance cases (Tom Lane)

The new code for taking the existence of a foreign key relationship into account did the wrong thing in these cases, making the estimates worse not better than the pre-9.6 code.

• Fix pg_dump to emit the data of a sequence that is marked as an extension configuration table (Michael Paquier)

• Fix mishandling of ALTER DEFAULT PRIVILEGES ... REVOKE in pg_dump (Stephen Frost)

pg_dump missed issuing the required REVOKE commands in cases where ALTER DEFAULT PRIVILEGES had been used to reduce privileges to less than they would normally be.

• Fix pg_dump to dump user-defined casts and transforms that use built-in functions (Stephen Frost)

• Fix pg_restore with --create --if-exists to behave more sanely if an archive contains unrecognized DROP commands (Tom Lane)

This doesn’t fix any live bug, but it may improve the behavior in future if pg_restore is used with an archive generated by a later pg_dump version.

• Fix pg_basebackup’s rate limiting in the presence of slow I/O (Antonin Houska)

If disk I/O was transiently much slower than the specified rate limit, the calculation overflowed, effectively disabling the rate limit for the rest of the run.

• Fix pg_basebackup’s handling of symlinked pg_stat_tmp and pg_replslot subdirectories (Magnus Hagander, Michael Paquier)
• Fix possible pg_basebackup failure on standby server when including WAL files (Amit Kapila, Robert Haas)

• Improve initdb to insert the correct platform-specific default values for the xxx_flush_after parameters into postgresql.conf (Fabien Coelho, Tom Lane)
   This is a cleaner way of documenting the default values than was used previously.

• Fix possible mishandling of expanded arrays in domain check constraints and CASE execution (Tom Lane)
   It was possible for a PL/pgSQL function invoked in these contexts to modify or even delete an array value that needs to be preserved for additional operations.

• Fix nested uses of PL/pgSQL functions in contexts such as domain check constraints evaluated during assignment to a PL/pgSQL variable (Tom Lane)

• Ensure that the Python exception objects we create for PL/Python are properly reference-counted (Rafa de la Torre, Tom Lane)
   This avoids failures if the objects are used after a Python garbage collection cycle has occurred.

• Fix PL/Tcl to support triggers on tables that have .tupno as a column name (Tom Lane)
   This matches the (previously undocumented) behavior of PL/Tcl’s spi_exec and spi_execp commands, namely that a magic .tupno column is inserted only if there isn’t a real column named that.

• Allow DOS-style line endings in ~/.pgpass files, even on Unix (Vik Fearing)
   This change simplifies use of the same password file across Unix and Windows machines.

• Fix one-byte buffer overrun if ecpg is given a file name that ends with a dot (Takayuki Tsunakawa)

• Fix incorrect error reporting for duplicate data in psql’s crosstabview (Tom Lane)
   psql sometimes quoted the wrong row and/or column values when complaining about multiple entries for the same crosstab cell.

• Fix psql’s tab completion for ALTER DEFAULT PRIVILEGES (Gilles Darold, Stephen Frost)

• Fix psql’s tab completion for ALTER TABLE t ALTER c DROP ... (Kyotaro Horiguchi)

• In psql, treat an empty or all-blank setting of the PAGER environment variable as meaning “no pager” (Tom Lane)
   Previously, such a setting caused output intended for the pager to vanish entirely.

• Improve contrib/dblink’s reporting of low-level libpq errors, such as out-of-memory (Joe Conway)

• Teach contrib/dblink to ignore irrelevant server options when it uses a contrib/postgres_fdw foreign server as the source of connection options (Corey Huinker)
   Previously, if the foreign server object had options that were not also libpq connection options, an error occurred.

• Fix portability problems in contrib/pageinspect’s functions for GIN indexes (Peter Eisentraut, Tom Lane)

• Fix possible miss of socket read events while waiting on Windows (Amit Kapila)
   This error was harmless for most uses, but it is known to cause hangs when trying to use the pldebugger extension.

• On Windows, ensure that environment variable changes are propagated to DLLs built with debug options (Christian Ullrich)
• Sync our copy of the timezone library with IANA release tzcode2016j (Tom Lane)

This fixes various issues, most notably that timezone data installation failed if the target directory didn’t support hard links.

• Update time zone data files to tzdata release 2016j for DST law changes in northern Cyprus (adding a new zone Asia/Famagusta), Russia (adding a new zone Europe/Saratov), Tonga, and Antarctica/Casey. Historical corrections for Italy, Kazakhstan, Malta, and Palestine. Switch to preferring numeric zone abbreviations for Tonga.

E.13. Release 9.6.1

Release date: 2016-10-27

This release contains a variety of fixes from 9.6.0. For information about new features in the 9.6 major release, see Section E.14.

E.13.1. Migration to Version 9.6.1

A dump/restore is not required for those running 9.6.X.

However, if your installation has been affected by the bugs described in the first two changelog entries below, then after updating you may need to take action to repair corrupted free space maps and/or visibility maps.

E.13.2. Changes

• Fix WAL-logging of truncation of relation free space maps and visibility maps (Pavan Deolasee, Heikki Linnakangas)

It was possible for these files to not be correctly restored during crash recovery, or to be written incorrectly on a standby server. Bogus entries in a free space map could lead to attempts to access pages that have been truncated away from the relation itself, typically producing errors like “could not read block xxx: read only 0 of 8192 bytes”. Checksum failures in the visibility map are also possible, if checksumming is enabled.

Procedures for determining whether there is a problem and repairing it if so are discussed at https://wiki.postgresql.org/wiki/Free_Space_Map_Problems.

• Fix possible data corruption when pg_upgrade rewrites a relation visibility map into 9.6 format (Tom Lane)

On big-endian machines, bytes of the new visibility map were written in the wrong order, leading to a completely incorrect map. On Windows, the old map was read using text mode, leading to incorrect results if the map happened to contain consecutive bytes that matched a carriage return/line feed sequence. The latter error would almost always lead to a pg_upgrade failure due to the map file appearing to be the wrong length.

If you are using a big-endian machine (many non-Intel architectures are big-endian) and have used pg_upgrade to upgrade from a pre-9.6 release, you should assume that all visibility maps are incorrect and need to be regenerated. It is sufficient to truncate each relation’s visibility map with
Appendix E. Release Notes

contrib/pg_visibility’s pg_truncate_visibility_map() function. For more information see https://wiki.postgresql.org/wiki/Visibility_Map_Problems.

- Don’t throw serialization errors for self-conflicting insertions in INSERT ... ON CONFLICT (Thomas Munro, Peter Geoghegan)
- Fix use-after-free hazard in execution of aggregate functions using DISTINCT (Peter Geoghegan)
  This could lead to a crash or incorrect query results.
- Fix incorrect handling of polymorphic aggregates used as window functions (Tom Lane)
  The aggregate’s transition function was told that its first argument and result were of the aggregate’s output type, rather than the state type. This led to errors or crashes with polymorphic transition functions.
- Fix COPY with a column name list from a table that has row-level security enabled (Adam Brightwell)
- Fix EXPLAIN to emit valid XML when track_io_timing is on (Markus Winand)
  Previously the XML output-format option produced syntactically invalid tags such as <I/O-Read-Time>. That is now rendered as <I-O-Read-Time>.
- Fix statistics update for TRUNCATE in a prepared transaction (Stas Kelvich)
- Fix bugs in merging inherited CHECK constraints while creating or altering a table (Tom Lane, Amit Langote)
  Allow identical CHECK constraints to be added to a parent and child table in either order. Prevent merging of a valid constraint from the parent table with a NOT VALID constraint on the child. Likewise, prevent merging of a NO INHERIT child constraint with an inherited constraint.
- Show a sensible value in pg_settings.unit for min_wal_size and max_wal_size (Tom Lane)
- Fix replacement of array elements in jsonb_set() (Tom Lane)
  If the target is an existing JSON array element, it got deleted instead of being replaced with a new value.
- Avoid very-low-probability data corruption due to testing tuple visibility without holding buffer lock (Thomas Munro, Peter Geoghegan, Tom Lane)
- Preserve commit timestamps across server restart (Julien Rouhaud, Craig Ringer)
  With track_commit_timestamp turned on, old commit timestamps became inaccessible after a clean server restart.
- Fix logical WAL decoding to work properly when a subtransaction’s WAL output is large enough to spill to disk (Andres Freund)
- Fix dangling-pointer problem in logical WAL decoding (Stas Kelvich)
- Round shared-memory allocation request to a multiple of the actual huge page size when attempting to use huge pages on Linux (Tom Lane)
  This avoids possible failures during munmap() on systems with atypical default huge page sizes. Except in crash-recovery cases, there were no ill effects other than a log message.
- Don’t try to share SSL contexts across multiple connections in libpq (Heikki Linnakangas)
  This led to assorted corner-case bugs, particularly when trying to use different SSL parameters for different connections.
- Avoid corner-case memory leak in libpq (Tom Lane)
The reported problem involved leaking an error report during PQreset(), but there might be related cases.

- In pg_upgrade, check library loadability in name order (Tom Lane)
  This is a workaround to deal with cross-extension dependencies from language transform modules to their base language and data type modules.
- Fix pg_upgrade to work correctly for extensions containing index access methods (Tom Lane)
  To allow this, the server has been extended to support ALTER EXTENSION ADD/DROP ACCESS METHOD. That functionality should have been included in the original patch to support dynamic creation of access methods, but it was overlooked.
- Improve error reporting in pg_upgrade’s file copying/linking/rewriting steps (Tom Lane, Álvaro Herrera)
- Fix pg_dump to work against pre-7.4 servers (Amit Langote, Tom Lane)
- Disallow specifying both --source-server and --source-target options to pg_rewind (Michael Banck)
- Make pg_rewind turn off synchronous_commit in its session on the source server (Michael Banck, Michael Paquier)
  This allows pg_rewind to work even when the source server is using synchronous replication that is not working for some reason.
- In pg_xlogdump, retry opening new WAL segments when using --follow option (Magnus Hagander)
  This allows for a possible delay in the server’s creation of the next segment.
- Fix contrib/pg_visibility to report the correct TID for a corrupt tuple that has been the subject of a rolled-back update (Tom Lane)
- Fix makefile dependencies so that parallel make of PL/Python by itself will succeed reliably (Pavel Raiskup)
- Update time zone data files to tzdata release 2016h for DST law changes in Palestine and Turkey, plus historical corrections for Turkey and some regions of Russia. Switch to numeric abbreviations for some time zones in Antarctica, the former Soviet Union, and Sri Lanka.
  The IANA time zone database previously provided textual abbreviations for all time zones, sometimes making up abbreviations that have little or no currency among the local population. They are in process of reversing that policy in favor of using numeric UTC offsets in zones where there is no evidence of real-world use of an English abbreviation. At least for the time being, PostgreSQL will continue to accept such removed abbreviations for timestamp input. But they will not be shown in the pg_timezone_names view nor used for output.
  In this update, AMT is no longer shown as being in use to mean Armenia Time. Therefore, we have changed the Default abbreviation set to interpret it as Amazon Time, thus UTC-4 not UTC+4.

E.14. Release 9.6

Release date: 2016-09-29
E.14.1. Overview

Major enhancements in PostgreSQL 9.6 include:

- Parallel execution of sequential scans, joins and aggregates
- Avoid scanning pages unnecessarily during vacuum freeze operations
- Synchronous replication now allows multiple standby servers for increased reliability
- Full-text search can now search for phrases (multiple adjacent words)
- `postgres_fdw` now supports remote joins, sorts, `UPDATES`, and `DELETES`
- Substantial performance improvements, especially in the area of scalability on multi-CPU-socket servers

The above items are explained in more detail in the sections below.

E.14.2. Migration to Version 9.6

A dump/restore using `pg_dumpall`, or use of `pg_upgrade`, is required for those wishing to migrate data from any previous release.

Version 9.6 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Improve the `pg_stat_activity` view’s information about what a process is waiting for (Amit Kapila, Ildus Kurbangaliev)
  Historically a process has only been shown as waiting if it was waiting for a heavyweight lock. Now waits for lightweight locks and buffer pins are also shown in `pg_stat_activity`. Also, the type of lock being waited for is now visible. These changes replace the `waiting` column with `wait_event_type` and `wait_event`.
- In `to_char()`, do not count a minus sign (when needed) as part of the field width for time-related fields (Bruce Momjian)
  For example, `to_char(‘-4 years’::interval, ’YY’) now returns -04, rather than -4.
- Make `extract()` behave more reasonably with infinite inputs (Vitaly Burovoy)
  Historically the `extract()` function just returned zero given an infinite timestamp, regardless of the given field name. Make it return `infinity` or `-infinity` as appropriate when the requested field is one that is monotonically increasing (e.g., `year`, `epoch`), or `NULL` when it is not (e.g., `day`, `hour`). Also, throw the expected error for bad field names.
- Remove PL/pgSQL’s “feature” that suppressed the innermost line of `CONTEXT` for messages emitted by `RAISE` commands (Pavel Stehule)
  This ancient backwards-compatibility hack was agreed to have outlived its usefulness.
- Fix the default text search parser to allow leading digits in `email` and `host` tokens (Artur Zakirov)
  In most cases this will result in few changes in the parsing of text. But if you have data where such addresses occur frequently, it may be worth rebuilding dependent `tsvector` columns and indexes so that addresses of this form will be found properly by text searches.
- Extend `contrib/unaccent`’s standard `unaccent.rules` file to handle all diacritics known to Unicode, and to expand ligatures correctly (Thomas Munro, Léonard Benedetti)
The previous version neglected to convert some less-common letters with diacritic marks. Also, ligatures are now expanded into separate letters. Installations that use this rules file may wish to rebuild `tsvector` columns and indexes that depend on the result.

- Remove the long-deprecated `CREATEUSER/NOCREATEUSER` options from `CREATE ROLE` and allied commands (Tom Lane)
  `CREATEUSER` actually meant `SUPERUSER`, for ancient backwards-compatibility reasons. This has been a constant source of confusion for people who (reasonably) expect it to mean `CREATEROLE`. It has been deprecated for ten years now, so fix the problem by removing it.

- Treat role names beginning with `pg_` as reserved (Stephen Frost)
  User creation of such role names is now disallowed. This prevents conflicts with built-in roles created by initdb.

- Change a column name in the `information_schema.routines` view from `result_cast_character_set_name` to `result_cast_char_set_name` (Clément Prévost)
  The SQL:2011 standard specifies the longer name, but that appears to be a mistake, because adjacent column names use the shorter style, as do other `information_schema` views.

- psql’s `-c` option no longer implies `--no-psqlrc` (Pavel Stehule, Catalin Iacob)
  Write `--no-psqlrc` (or its abbreviation `-X`) explicitly to obtain the old behavior. Scripts so modified will still work with old versions of psql.

- Improve `pg_restore`’s `-t` option to match all types of relations, not only plain tables (Craig Ringer)

- Change the display format used for `NextXID` in `pg_controldata` and related places (Joe Conway, Bruce Momjian)
  Display epoch-and-transaction-ID values in the format `number:number`. The previous format `number/number` was confusingly similar to that used for LSNs.

- Update extension functions to be marked parallel-safe where appropriate (Andreas Karlsson)
  Many of the standard extensions have been updated to allow their functions to be executed within parallel query worker processes. These changes will not take effect in databases `pg_upgrade`’d from prior versions unless you apply `ALTER EXTENSION UPDATE` to each such extension (in each database of a cluster).

**E.14.3. Changes**

Below you will find a detailed account of the changes between PostgreSQL 9.6 and the previous major release.

**E.14.3.1. Server**

**E.14.3.1.1. Parallel Queries**

- Parallel queries (Robert Haas, Amit Kapila, David Rowley, many others)
  With 9.6, PostgreSQL introduces initial support for parallel execution of large queries. Only strictly read-only queries where the driving table is accessed via a sequential scan can be parallelized. Hash joins and nested loops can be performed in parallel, as can aggregation (for supported aggregates). Much remains to be done, but this is already a useful set of features.
Parallel query execution is not (yet) enabled by default. To allow it, set the new configuration parameter `max_parallel_workers_per_gather` to a value larger than zero. Additional control over use of parallelism is available through other new configuration parameters `force_parallel_mode`, `parallel_setup_cost`, `parallel_tuple_cost`, and `min_parallel_relation_size`.

- Provide infrastructure for marking the parallel-safety status of functions (Robert Haas, Amit Kapila)

### E.14.3.1.2. Indexes

- Allow GIN index builds to make effective use of maintenance_work_mem settings larger than 1 GB (Robert Abraham, Teodor Sigaev)
- Add pages deleted from a GIN index’s pending list to the free space map immediately (Jeff Janes, Teodor Sigaev)
  This reduces bloat if the table is not vacuumed often.
- Add `gin_clean_pending_list()` function to allow manual invocation of pending-list cleanup for a GIN index (Jeff Janes)
  Formerly, such cleanup happened only as a byproduct of vacuuming or analyzing the parent table.
- Improve handling of dead index tuples in GiST indexes (Anastasia Lubennikova)
  Dead index tuples are now marked as such when an index scan notices that the corresponding heap tuple is dead. When inserting tuples, marked-dead tuples will be removed if needed to make space on the page.
- Add an SP-GiST operator class for type `box` (Alexander Lebedev)

### E.14.3.1.3. Sorting

- Improve sorting performance by using quicksort, not replacement selection sort, when performing external sort steps (Peter Geoghegan)
  The new approach makes better use of the CPU cache for typical cache sizes and data volumes. Where necessary, the behavior can be adjusted via the new configuration parameter `replacement_sort_tuples`.
- Speed up text sorts where the same string occurs multiple times (Peter Geoghegan)
- Speed up sorting of `uuid`, `bytea`, and `char(n)` fields by using “abbreviated” keys (Peter Geoghegan)
  Support for abbreviated keys has also been added to the non-default operator classes `text_pattern_ops`, `varchar_pattern_ops`, and `bpchar_pattern_ops`. Processing of ordered-set aggregates can also now exploit abbreviated keys.
- Speed up `CREATE INDEX CONCURRENTLY` by treating TIDs as 64-bit integers during sorting (Peter Geoghegan)

### E.14.3.1.4. Locking

- Reduce contention for the `ProcArrayLock` (Amit Kapila, Robert Haas)
Appendix E. Release Notes

- Improve performance by moving buffer content locks into the buffer descriptors (Andres Freund, Simon Riggs)
- Replace shared-buffer header spinlocks with atomic operations to improve scalability (Alexander Korotkov, Andres Freund)
- Use atomic operations, rather than a spinlock, to protect an LWLock’s wait queue (Andres Freund)
- Partition the shared hash table freelist to reduce contention on multi-CPU-socket servers (Alexander Alekseev)
- Reduce interlocking on standby servers during the replay of btree index vacuuming operations (Simon Riggs)

This change avoids substantial replication delays that sometimes occurred while replaying such operations.

E.14.3.1.5. Optimizer Statistics

- Improve `ANALYZE`’s estimates for columns with many nulls (Tomas Vondra, Alex Shulgin)

  Previously `ANALYZE` tended to underestimate the number of non-NULL distinct values in a column with many NULLs, and was also inaccurate in computing the most-common values.

- Improve planner’s estimate of the number of distinct values in a query result (Tomas Vondra)

- Use foreign key relationships to infer selectivity for join predicates (Tomas Vondra, David Rowley)

  If a table t has a foreign key restriction, say (a,b) REFERENCES r (x,y), then a WHERE condition such as t.a = r.x AND t.b = r.y cannot select more than one r row per t row. The planner formerly considered these AND conditions to be independent and would often drastically misestimate selectivity as a result. Now it compares the WHERE conditions to applicable foreign key constraints and produces better estimates.

E.14.3.1.6. VACUUM

- Avoid re-vacuuming pages containing only frozen tuples (Masahiko Sawada, Robert Haas, Andres Freund)

  Formerly, anti-wraparound vacuum had to visit every page of a table, even pages where there was nothing to do. Now, pages containing only already-frozen tuples are identified in the table’s visibility map, and can be skipped by vacuum even when doing transaction wraparound prevention. This should greatly reduce the cost of maintaining large tables containing mostly-unchanging data.

  If necessary, vacuum can be forced to process all-frozen pages using the new `DISABLE_PAGE_SKIPPING` option. Normally this should never be needed, but it might help in recovering from visibility-map corruption.

- Avoid useless heap-truncation attempts during VACUUM (Jeff Janes, Tom Lane)

  This change avoids taking an exclusive table lock in some cases where no truncation is possible. The main benefit comes from avoiding unnecessary query cancellations on standby servers.

E.14.3.1.7. General Performance

- Allow old MVCC snapshots to be invalidated after a configurable timeout (Kevin Grittner)
Appendix E. Release Notes

Normally, deleted tuples cannot be physically removed by vacuuming until the last transaction that could “see” them is gone. A transaction that stays open for a long time can thus cause considerable table bloat because space cannot be recycled. This feature allows setting a time-based limit, via the new configuration parameter old_snapshot_threshold, on how long an MVCC snapshot is guaranteed to be valid. After that, dead tuples are candidates for removal. A transaction using an outdated snapshot will get an error if it attempts to read a page that potentially could have contained such data.

- Ignore GROUP BY columns that are functionally dependent on other columns (David Rowley)

If a GROUP BY clause includes all columns of a non-deferred primary key, as well as other columns of the same table, those other columns are redundant and can be dropped from the grouping. This saves computation in many common cases.

- Allow use of an index-only scan on a partial index when the index’s WHERE clause references columns that are not indexed (Tomas Vondra, Kyotaro Horiguchi)

For example, an index defined by CREATE INDEX tidx_partial ON t(b) WHERE a > 0 can now be used for an index-only scan by a query that specifies WHERE a > 0 and does not otherwise use a. Previously this was disallowed because a is not listed as an index column.

- Perform checkpoint writes in sorted order (Fabien Coelho, Andres Freund)

Previously, checkpoints wrote out dirty pages in whatever order they happen to appear in shared buffers, which usually is nearly random. That performs poorly, especially on rotating media. This change causes checkpoint-driven writes to be done in order by file and block number, and to be balanced across tablespaces.

- Where feasible, trigger kernel writeback after a configurable number of writes, to prevent accumulation of dirty data in kernel disk buffers (Fabien Coelho, Andres Freund)

PostgreSQL writes data to the kernel’s disk cache, from where it will be flushed to physical storage in due time. Many operating systems are not smart about managing this and allow large amounts of dirty data to accumulate before deciding to flush it all at once, causing long delays for new I/O requests until the flushing finishes. This change attempts to alleviate this problem by explicitly requesting data flushes after a configurable interval.

On Linux, sync_file_range() is used for this purpose, and the feature is on by default on Linux because that function has few downsides. This flushing capability is also available on other platforms if they have msync() or posix_fadvise(), but those interfaces have some undesirable side-effects so the feature is disabled by default on non-Linux platforms.

The new configuration parameters backend_flush_after, bgwriter_flush_after, checkpoint_flush_after, and wal_writer_flush_after control this behavior.

- Improve aggregate-function performance by sharing calculations across multiple aggregates if they have the same arguments and transition functions (David Rowley)

For example, SELECT AVG(x), VARIANCE(x) FROM tab can use a single per-row computation for both aggregates.

- Speed up visibility tests for recently-created tuples by checking the current transaction’s snapshot, not pg_clog, to decide if the source transaction should be considered committed (Jeff Janes, Tom Lane)

- Allow tuple hint bits to be set sooner than before (Andres Freund)

- Improve performance of short-lived prepared transactions (Stas Kelvich, Simon Riggs, Pavan Deolasee)
Two-phase commit information is now written only to WAL during PREPARE TRANSACTION, and will be read back from WAL during COMMIT PREPARED if that happens soon thereafter. A separate state file is created only if the pending transaction does not get committed or aborted by the time of the next checkpoint.

- Improve performance of memory context destruction (Jan Wieck)
- Improve performance of resource owners with many tracked objects (Aleksander Alekseev)
- Improve speed of the output functions for timestamp, time, and date data types (David Rowley, Andres Freund)
- Avoid some unnecessary cancellations of hot-standby queries during replay of actions that take AccessExclusive locks (Jeff Janes)
- Extend relations multiple blocks at a time when there is contention for the relation’s extension lock (Dilip Kumar)

This improves scalability by decreasing contention.

- Increase the number of clog buffers for better scalability (Amit Kapila, Andres Freund)
- Speed up expression evaluation in PL/pgSQL by keeping ParamListInfo entries for simple variables valid at all times (Tom Lane)
- Avoid reducing the SO_SNDBUF setting below its default on recent Windows versions (Chen Hua-jun)
- Disable update_process_title by default on Windows (Takayuki Tsunakawa)

The overhead of updating the process title is much larger on Windows than most other platforms, and it is also less useful to do it since most Windows users do not have tools that can display process titles.

**E.14.3.1.8. Monitoring**

- Add pg_stat_progress_vacuum system view to provide progress reporting for VACUUM operations (Amit Langote, Robert Haas, Vinayak Pokale, Rahila Syed)
- Add pg_control_system(), pg_control_checkpoint(), pg_control_recovery(), and pg_control_init() functions to expose fields of pg_control to SQL (Joe Conway, Michael Paquier)
- Add pg_config system view (Joe Conway)

This view exposes the same information available from the pg_config command-line utility, namely assorted compile-time configuration information for PostgreSQL.

- Add a confirmed_flush_lsn column to the pg_replication_slots system view (Marko Tiikkaja)
- Add pg_stat_wal_receiver system view to provide information about the state of a hot-standby server’s WAL receiver process (Michael Paquier)
- Add pg_blocking_pids() function to reliably identify which sessions block which others (Tom Lane)

This function returns an array of the process IDs of any sessions that are blocking the session with the given process ID. Historically users have obtained such information using a self-join on the pg_locks view. However, it is unreasonably tedious to do it that way with any modicum of correctness, and the addition of parallel queries has made the old approach entirely impractical,
Appendix E. Release Notes

since locks might be held or awaited by child worker processes rather than the session’s main process.

- Add function `pg_current_xlog_flush_location()` to expose the current transaction log flush location (Tomas Vondra)
- Add function `pg_notification_queue_usage()` to report how full the NOTIFY queue is (Brendan Jurd)
- Limit the verbosity of memory context statistics dumps (Tom Lane)

The memory usage dump that is output to the postmaster log during an out-of-memory failure now summarizes statistics when there are a large number of memory contexts, rather than possibly generating a very large report. There is also a “grand total” summary line now.

E.14.3.1.9. Authentication

- Add a BSD authentication method to allow use of the BSD Authentication service for PostgreSQL client authentication (Marisa Emerson)
  BSD Authentication is currently only available on OpenBSD.
- When using PAM authentication, provide the client IP address or host name to PAM modules via the `PAM_RHOST` item (Grzegorz Sampolski)
- Provide detail in the postmaster log for more types of password authentication failure (Tom Lane)
  All ordinarily-reachable password authentication failure cases should now provide specific `DETAIL` fields in the log.
- Support RADIUS passwords up to 128 characters long (Marko Tiikkaja)
- Add new SSPI authentication parameters `compat_realm` and `upn_username` to control whether NetBIOS or Kerberos realm names and user names are used during SSPI authentication (Christian Ullrich)

E.14.3.1.10. Server Configuration

- Allow sessions to be terminated automatically if they are in idle-in-transaction state for too long (Vik Fearing)
  This behavior is controlled by the new configuration parameter `idle_in_transaction_session_timeout`. It can be useful to prevent forgotten transactions from holding locks or preventing vacuum cleanup for too long.
- Raise the maximum allowed value of `checkpoint_timeout` to 24 hours (Simon Riggs)
- Allow `effective_io_concurrency` to be set per-tablespace to support cases where different tablespaces have different I/O characteristics (Julien Rouhaud)
- Add `log_line_prefix` option `%n` to print the current time in Unix epoch form, with milliseconds (Tomas Vondra, Jeff Davis)
- Add `syslog_sequence_numbers` and `syslog_split_messages` configuration parameters to provide more control over the message format when logging to syslog (Peter Eisentraut)
- Merge the `archive` and `hot_standby` values of the `wal_level` configuration parameter into a single new value `replica` (Peter Eisentraut)
Making a distinction between these settings is no longer useful, and merging them is a step towards a planned future simplification of replication setup. The old names are still accepted but are converted to replica internally.

- Add configure option --with-systemd to enable calling sd_notify() at server start and stop (Peter Eisentraut)

This allows the use of systemd service units of type notify, which greatly simplifies the management of PostgreSQL under systemd.

- Allow the server’s SSL key file to have group read access if it is owned by root (Christoph Berg)

Formerly, we insisted the key file be owned by the user running the PostgreSQL server, but that is inconvenient on some systems (such as Debian) that are configured to manage certificates centrally. Therefore, allow the case where the key file is owned by root and has group read access. It is up to the operating system administrator to ensure that the group does not include any untrusted users.

**E.14.3.1.11. Reliability**

- Force backends to exit if the postmaster dies (Rajeev Rastogi, Robert Haas)

Under normal circumstances the postmaster should always outlive its child processes. If for some reason the postmaster dies, force backend sessions to exit with an error. Formerly, existing backends would continue to run until their clients disconnect, but that is unsafe and inefficient. It also prevents a new postmaster from being started until the last old backend has exited. Backends will detect postmaster death when waiting for client I/O, so the exit will not be instantaneous, but it should happen no later than the end of the current query.

- Check for serializability conflicts before reporting constraint-violation failures (Thomas Munro)

When using serializable transaction isolation, it is desirable that any error due to concurrent transactions should manifest as a serialization failure, thereby cueing the application that a retry might succeed. Unfortunately, this does not reliably happen for duplicate-key failures caused by concurrent insertions. This change ensures that such an error will be reported as a serialization error if the application explicitly checked for the presence of a conflicting key (and did not find it) earlier in the transaction.

- Ensure that invalidation messages are recorded in WAL even when issued by a transaction that has no XID assigned (Andres Freund)

This fixes some corner cases in which transactions on standby servers failed to notice changes, such as new indexes.

- Prevent multiple processes from trying to clean a GIN index’s pending list concurrently (Teodor Sigaev, Jeff Janes)

This had been intentionally allowed, but it causes race conditions that can result in vacuum missing index entries it needs to delete.

**E.14.3.2. Replication and Recovery**

- Allow synchronous replication to support multiple simultaneous synchronous standby servers, not just one (Masahiko Sawada, Beena Emerson, Michael Paquier, Fujii Masao, Kyotaro Horiguchi)

The number of standby servers that must acknowledge a commit before it is considered complete is now configurable as part of the synchronous_standby_names parameter.
Appendix E. Release Notes

• Add new setting `remote_apply` for configuration parameter `synchronous_commit` (Thomas Munro)

  In this mode, the master waits for the transaction to be applied on the standby server, not just written to disk. That means that you can count on a transaction started on the standby to see all commits previously acknowledged by the master.

• Add a feature to the replication protocol, and a corresponding option to `pg_create_physical_replication_slot()`, to allow reserving WAL immediately when creating a replication slot (Gurjeet Singh, Michael Paquier)

  This allows the creation of a replication slot to guarantee that all the WAL needed for a base backup will be available.

• Add a `--slot` option to `pg_basebackup` (Peter Eisentraut)

  This lets `pg_basebackup` use a replication slot defined for WAL streaming. After the base backup completes, selecting the same slot for regular streaming replication allows seamless startup of the new standby server.

• Extend `pg_start_backup()` and `pg_stop_backup()` to support non-exclusive backups (Magnus Hagander)

E.14.3.3. Queries

• Allow functions that return sets of tuples to return simple `NULL`s (Andrew Gierth, Tom Lane)

  In the context of `SELECT FROM function(...)`, a function that returned a set of composite values was previously not allowed to return a plain `NULL` value as part of the set. Now that is allowed and interpreted as a row of `NULL`s. This avoids corner-case errors with, for example, unnesting an array of composite values.

• Fully support array subscripts and field selections in the target column list of an `INSERT` with multiple `VALUES` rows (Tom Lane)

  Previously, such cases failed if the same target column was mentioned more than once, e.g., `INSERT INTO tab (x[1], x[2]) VALUES (...)`.

• When appropriate, postpone evaluation of `SELECT` output expressions until after an `ORDER BY` sort (Konstantin Knizhnik)

  This change ensures that volatile or expensive functions in the output list are executed in the order suggested by `ORDER BY`, and that they are not evaluated more times than required when there is a `LIMIT` clause. Previously, these properties held if the ordering was performed by an index scan or pre-merge-join sort, but not if it was performed by a top-level sort.

• Widen counters recording the number of tuples processed to 64 bits (Andreas Scherbaum)

  This change allows command tags, e.g. `SELECT`, to correctly report tuple counts larger than 4 billion. This also applies to PL/pgSQL’s `GET DIAGNOSTICS ... ROW_COUNT` command.

• Avoid doing encoding conversions by converting through the `MULE_INTERNAL` encoding (Tom Lane)

  Previously, many conversions for Cyrillic and Central European single-byte encodings were done by converting to a related `MULE_INTERNAL` coding scheme and then to the destination encoding. Aside from being inefficient, this meant that when the conversion encountered an untranslatable character, the error message would confusingly complain about failure to convert to or from `MULE_INTERNAL`, rather than the user-visible encoding.
Consider performing joins of foreign tables remotely only when the tables will be accessed under the same role ID (Shigeru Hanada, Ashutosh Bapat, Etsuro Fujita)

Previously, the foreign join pushdown infrastructure left the question of security entirely up to individual foreign data wrappers, but that made it too easy for an FDW to inadvertently create subtle security holes. So, make it the core code’s job to determine which role ID will access each table, and do not attempt join pushdown unless the role is the same for all relevant relations.

E.14.3.4. Utility Commands

• Allow COPY to copy the output of an INSERT/UPDATE/DELETE ... RETURNING query (Marko Tikka)

Previously, an intermediate CTE had to be written to get this result.

• Introduce ALTER object DEPENDS ON EXTENSION (Abhijit Menon-Sen)

This command allows a database object to be marked as depending on an extension, so that it will be dropped automatically if the extension is dropped (without needing CASCADE). However, the object is not part of the extension, and thus will be dumped separately by pg_dump.

• Make ALTER object SET SCHEMA do nothing when the object is already in the requested schema, rather than throwing an error as it historically has for most object types (Marti Raudsepp)

• Add options to ALTER OPERATOR to allow changing the selectivity functions associated with an existing operator (Yury Zhuravlev)

• Add an IF NOT EXISTS option to ALTER TABLE ADD COLUMN (Fabrizio de Royes Mello)

• Reduce the lock strength needed by ALTER TABLE when setting fillfactor and autovacuum-related relation options (Fabrizio de Royes Mello, Simon Riggs)

• Introduce CREATE ACCESS METHOD to allow extensions to create index access methods (Alexander Korotkov, Petr Jelinek)

• Add a CASCADE option to CREATE EXTENSION to automatically create any extensions the requested one depends on (Petr Jelinek)

• Make CREATE TABLE ... LIKE include an OID column if any source table has one (Bruce Momjian)

• If a CHECK constraint is declared NOT VALID in a table creation command, automatically mark it as valid (Amit Langote, Amul Sul)

This is safe because the table has no existing rows. This matches the longstanding behavior of FOREIGN KEY constraints.

• Fix DROP OPERATOR to clear pg_operator.oprcom and pg_operator.oprnegate links to the dropped operator (Roma Sokolov)

Formerly such links were left as-is, which could pose a problem in the somewhat unlikely event that the dropped operator’s OID was reused for another operator.

• Do not show the same subplan twice in EXPLAIN output (Tom Lane)

In certain cases, typically involving SubPlan nodes in index conditions, EXPLAIN would print data for the same subplan twice.

• Disallow creation of indexes on system columns, except for OID columns (David Rowley)
Such indexes were never considered supported, and would very possibly misbehave since the system might change the system-column fields of a tuple without updating indexes. However, previously there were no error checks to prevent them from being created.

E.14.3.5. Permissions Management

- Use the privilege system to manage access to sensitive functions (Stephen Frost)

Formerly, many security-sensitive functions contained hard-wired checks that would throw an error if they were called by a non-superuser. This forced the use of superuser roles for some relatively pedestrian tasks. The hard-wired error checks are now gone in favor of making \texttt{\texttt{initdb}} revoke the default public \texttt{EXECUTE} privilege on these functions. This allows installations to choose to grant usage of such functions to trusted roles that do not need all superuser privileges.

- Create some built-in roles that can be used to grant access to what were previously superuser-only functions (Stephen Frost)

Currently the only such role is \texttt{pg\_signal\_backend}, but more are expected to be added in future.

E.14.3.6. Data Types

- Improve full-text search to support searching for phrases, that is, lexemes appearing adjacent to each other in a specific order, or with a specified distance between them (Teodor Sigaev, Oleg Bartunov, Dmitry Ivanov)

A phrase-search query can be specified in \texttt{tsquery} input using the new operators \texttt{<->} and \texttt{<N>}. The former means that the lexemes before and after it must appear adjacent to each other in that order. The latter means they must be exactly \textit{N} lexemes apart.

- Allow omitting one or both boundaries in an array slice specifier, e.g. \texttt{array\_col[3:]} (Yury Zhuravlev)

Omitted boundaries are taken as the upper or lower limit of the corresponding array subscript. This allows simpler specification for many common use-cases.

- Be more careful about out-of-range dates and timestamps (Vitaly Burovoy)

This change prevents unexpected out-of-range errors for \texttt{timestamp with time zone} values very close to the implementation limits. Previously, the “same” value might be accepted or not depending on the \texttt{timezone} setting, meaning that a dump and reload could fail on a value that had been accepted when presented. Now the limits are enforced according to the equivalent UTC time, not local time, so as to be independent of \texttt{timezone}.

Also, PostgreSQL is now more careful to detect overflow in operations that compute new date or timestamp values, such as \texttt{date + integer}.

- For geometric data types, make sure \texttt{infinity} and \texttt{NaN} component values are treated consistently during input and output (Tom Lane)

Such values will now always print the same as they would in a simple \texttt{float8} column, and be accepted the same way on input. Previously the behavior was platform-dependent.

- Upgrade the \texttt{ispell} dictionary type to handle modern Hunspell files and support more languages (Artur Zakirov)

- Implement look-behind constraints in regular expressions (Tom Lane)
A look-behind constraint is like a lookahead constraint in that it consumes no text; but it checks for existence (or nonexistence) of a match ending at the current point in the string, rather than one starting at the current point. Similar features exist in many other regular-expression engines.

- In regular expressions, if an apparent three-digit octal escape \nnn would exceed 377 (255 decimal), assume it is a two-digit octal escape instead (Tom Lane)
  This makes the behavior match current Tcl releases.
- Add transaction ID operators xid<> xid and xid<> int4, for consistency with the corresponding equality operators (Michael Paquier)

### E.14.3.7. Functions

- Add \texttt{jsonb\_insert()} function to insert a new element into a \texttt{jsonb} array, or a not-previous- existing key into a \texttt{jsonb} object (Dmitry Dolgov)
- Improve the accuracy of the \texttt{ln()}, \texttt{log()}, \texttt{exp()}, and \texttt{pow()} functions for type \texttt{numeric} (Dean Rasheed)
- Add a \texttt{scale(numeric)} function to extract the display scale of a \texttt{numeric} value (Marko Tiikkaja)
- Add trigonometric functions that work in degrees (Dean Rasheed)
  For example, \texttt{sind()} measures its argument in degrees, whereas \texttt{sin()} measures in radians. These functions go to some lengths to deliver exact results for values where an exact result can be expected, for instance \texttt{sind(30) = 0.5}.
- Ensure that trigonometric functions handle infinity and NaN inputs per the POSIX standard (Dean Rasheed)
  The POSIX standard says that these functions should return NaN for NaN input, and should throw an error for out-of-range inputs including infinity. Previously our behavior varied across platforms.
- Make \texttt{to\_timestamp(float8)} convert float infinity to timestamp infinity (Vitaly Burovoy)
  Formerly it just failed on an infinite input.
- Add new functions for tsvector data (Stas Kelvich)
  The new functions are \texttt{ts\_delete()}, \texttt{ts\_filter()}, \texttt{unnest()}, \texttt{tsvector\_to\_array()}, \texttt{array\_to\_tsvector()}, and a variant of \texttt{setweight()} that sets the weight only for specified lexeme(s).
- Allow \texttt{ts\_stat()} and \texttt{tsvector\_update\_trigger()} to operate on values that are of types binary-compatible with the expected argument type, not just exactly that type; for example allow citext where text is expected (Teodor Sigaev)
- Add variadic functions \texttt{num\_nulls()} and \texttt{num\_nonnulls()} that count the number of their arguments that are null or non-null (Marko Tiikkaja)
  An example usage is \texttt{CHECK(num\_nonnulls(a,b,c) = 1)} which asserts that exactly one of a,b,c is not NULL. These functions can also be used to count the number of null or nonnull elements in an array.
- Add function \texttt{parse\_ident()} to split a qualified, possibly quoted SQL identifier into its parts (Pavel Stehule)
- In \texttt{to\_number()}, interpret a \texttt{V} format code as dividing by 10 to the power of the number of digits following \texttt{V} (Bruce Momjian)
Appendix E. Release Notes

This makes it operate in an inverse fashion to `to_char()`.

- Make the `to_reg*()` functions accept type `text` not `cstring` (Petr Korobeinikov)
  This avoids the need to write an explicit cast in most cases where the argument is not a simple literal constant.

- Add `pg_size_bytes()` function to convert human-readable size strings to numbers (Pavel Stehule, Vitaly Burovoy, Dean Rasheed)
  This function converts strings like those produced by `pg_size_pretty()` into bytes. An example usage is `SELECT oid::regclass FROM pg_class WHERE pg_total_relation_size(oid) > pg_size_bytes('10 GB')`.

- In `pg_size_pretty()`, format negative numbers similarly to positive ones (Adrian Vondendriesch)
  Previously, negative numbers were never abbreviated, just printed in bytes.

- Add an optional `missing_ok` argument to the `current_setting()` function (David Christensen)
  This allows avoiding an error for an unrecognized parameter name, instead returning a `NULL`.

- Change various catalog-inspection functions to return `NULL` for invalid input (Michael Paquier)
  `pg_get_viewdef()` now returns `NULL` if given an invalid view `OID`, and several similar functions likewise return `NULL` for bad input. Previously, such cases usually led to “cache lookup failed” errors, which are not meant to occur in user-facing cases.

- Fix `pg_replication_origin_xact_reset()` to not have any arguments (Fujii Masao)
  The documentation said that it has no arguments, and the C code did not expect any arguments, but the entry in `pg_proc` mistakenly specified two arguments.

E.14.3.8. Server-Side Languages

- In PL/pgSQL, detect mismatched `CONTINUE` and `EXIT` statements while compiling a function, rather than at execution time (Jim Nasby)

- Extend PL/Python’s error-reporting and message-reporting functions to allow specifying additional message fields besides the primary error message (Pavel Stehule)

- Allow PL/Python functions to call themselves recursively via SPI, and fix the behavior when multiple set-returning PL/Python functions are called within one query (Alexey Grishchenko, Tom Lane)

- Fix session-lifespan memory leaks in PL/Python (Heikki Linnakangas, Haribabu Kommi, Tom Lane)

- Modernize PL/Tcl to use Tcl’s “object” APIs instead of simple strings (Jim Nasby, Karl Lehenbauer)
  This can improve performance substantially in some cases. Note that PL/Tcl now requires Tcl 8.4 or later.

- In PL/Tcl, make database-reported errors return additional information in Tcl’s `errorCode` global variable (Jim Nasby, Tom Lane)
  This feature follows the Tcl convention for returning auxiliary data about an error.
Appendix E. Release Notes

- Fix PL/Tcl to perform encoding conversion between the database encoding and UTF-8, which is what Tcl expects (Tom Lane)

  Previously, strings were passed through without conversion, leading to misbehavior with non-ASCII characters when the database encoding was not UTF-8.

E.14.3.9. Client Interfaces

- Add a nonlocalized version of the severity field in error and notice messages (Tom Lane)

  This change allows client code to determine severity of an error or notice without having to worry about localized variants of the severity strings.

- Introduce a feature in libpq whereby the CONTEXT field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)

  The default behavior of PQerrorMessage() is now to print CONTEXT only for errors. The new function PQsetErrorContextVisibility() can be used to adjust this.

- Add support in libpq for regenerating an error message with a different verbosity level (Alex Shulgin)

  This is done with the new function PQresultVerboseErrorMessage(). This supports psql’s new \errverbose feature, and may be useful for other clients as well.

- Improve libpq’s PQhost() function to return useful data for default Unix-socket connections (Tom Lane)

  Previously it would return NULL if no explicit host specification had been given; now it returns the default socket directory path.

- Fix ecpg’s lexer to handle line breaks within comments starting on preprocessor directive lines (Michael Meskes)

E.14.3.10. Client Applications

- Add a --strict-names option to pg_dump and pg_restore (Pavel Stehule)

  This option causes the program to complain if there is no match for a -t or -n option, rather than silently doing nothing.

- In pg_dump, dump locally-made changes of privilege assignments for system objects (Stephen Frost)

  While it has always been possible for a superuser to change the privilege assignments for built-in or extension-created objects, such changes were formerly lost in a dump and reload. Now, pg_dump recognizes and dumps such changes. (This works only when dumping from a 9.6 or later server, however.)

- Allow pg_dump to dump non-extension-owned objects that are within an extension-owned schema (Martín Marqués)

  Previously such objects were ignored because they were mistakenly assumed to belong to the extension owning their schema.

- In pg_dump output, include the table name in object tags for object types that are only uniquely named per-table (for example, triggers) (Peter Eisentraut)
Appendix E. Release Notes

E.14.3.10.1. psql

- Support multiple \-c and \-f command-line options (Pavel Stehule, Catalin Iacob)
  
The specified operations are carried out in the order in which the options are given, and then psql terminates.

- Add a \crosstabview command that prints the results of a query in a cross-tabulated display (Daniel Vérité)
  
  In the crosstab display, data values from one query result column are placed in a grid whose column and row headers come from other query result columns.

- Add an \errverbose command that shows the last server error at full verbosity (Alex Shulgin)
  
  This is useful after getting an unexpected error — you no longer need to adjust the VERBOSITY variable and recreate the failure in order to see error fields that are not shown by default.

- Add \ev and \sv commands for editing and showing view definitions (Petr Korobeinikov)
  
  These are parallel to the existing \ef and \sf commands for functions.

- Add a \gexec command that executes a query and re-submits the result(s) as new queries (Corey Huinker)

- Allow \pset C string to set the table title, for consistency with \C string (Bruce Momjian)

- In \pset expanded auto mode, do not use expanded format for query results with only one column (Andreas Karlsson, Robert Haas)

- Improve the headers output by the \watch command (Michael Paquier, Tom Lane)
  
  Include the \pset title string if one has been set, and shorten the prefabricated part of the header to be timestamp (every Ns). Also, the timestamp format now obeys psql’s locale environment.

- Improve tab-completion logic to consider the entire input query, not only the current line (Tom Lane)
  
  Previously, breaking a command into multiple lines defeated any tab completion rules that needed to see words on earlier lines.

- Numerous minor improvements in tab-completion behavior (Peter Eisentraut, Vik Fearing, Kevin Grittner, Kyotaro Horiguchi, Jeff Janes, Andreas Karlsson, Fujii Masao, Thomas Munro, Masahiko Sawada, Pavel Stehule)

- Add a PROMPT option %p to insert the process ID of the connected backend (Julien Rouhaud)

- Introduce a feature whereby the CONTEXT field of messages can be suppressed, either always or only for non-error messages (Pavel Stehule)
  
  Printing CONTEXT only for errors is now the default behavior. This can be changed by setting the special variable SHOW_CONTEXT.

- Make \df+ show function access privileges and parallel-safety attributes (Michael Paquier)

E.14.3.10.2. pgbench

- SQL commands in pgbench scripts are now ended by semicolons, not newlines (Kyotaro Horiguchi, Tom Lane)
  
  This change allows SQL commands in scripts to span multiple lines. Existing custom scripts will need to be modified to add a semicolon at the end of each line that does not have one already. (Doing so does not break the script for use with older versions of pgbench.)
• Support floating-point arithmetic, as well as some built-in functions, in expressions in backslash commands (Fabien Coelho)

• Replace \setrandom with built-in functions (Fabien Coelho)
  
  The new built-in functions include `random()`, `random_exponential()`, and `random_gaussian()`, which perform the same work as \setrandom, but are easier to use since they can be embedded in larger expressions. Since these additions have made \setrandom obsolete, remove it.

• Allow invocation of multiple copies of the built-in scripts, not only custom scripts (Fabien Coelho)
  
  This is done with the new `-b` switch, which works similarly to `-f` for custom scripts.

• Allow changing the selection probabilities (weights) for scripts (Fabien Coelho)
  
  When multiple scripts are specified, each pgbench transaction randomly chooses one to execute. Formerly this was always done with uniform probability, but now different selection probabilities can be specified for different scripts.

• Collect statistics for each script in a multi-script run (Fabien Coelho)
  
  This feature adds an intermediate level of detail to existing global and per-command statistics printouts.

• Add a `--progress-timestamp` option to report progress with Unix epoch timestamps, instead of time since the run started (Fabien Coelho)

• Allow the number of client connections (`-c`) to not be an exact multiple of the number of threads (`-j`) (Fabien Coelho)

• When the `-T` option is used, stop promptly at the end of the specified time (Fabien Coelho)
  
  Previously, specifying a low transaction rate could cause pgbench to wait significantly longer than specified.

E.14.3.11. Server Applications

• Improve error reporting during initdb’s post-bootstrap phase (Tom Lane)
  
  Previously, an error here led to reporting the entire input file as the “failing query”; now just the current query is reported. To get the desired behavior, queries in initdb’s input files must be separated by blank lines.

• Speed up initdb by using just one standalone-backend session for all the post-bootstrap steps (Tom Lane)

• Improve pg_rewind so that it can work when the target timeline changes (Alexander Korotkov)
  
  This allows, for example, rewinding a promoted standby back to some state of the old master’s timeline.

• Remove obsolete `heap_formtuple/heap_modifytuple/heap_deformtuple` functions (Peter Geoghegan)

• Add macros to make `AllocSetContextCreate()` calls simpler and safer (Tom Lane)
Appendix E. Release Notes

Writing out the individual sizing parameters for a memory context is now deprecated in favor of using one of the new macros `ALLOCSET_DEFAULT_SIZES`, `ALLOCSET_SMALL_SIZES`, or `ALLOCSET_START_SMALL_SIZES`. Existing code continues to work, however.

- Unconditionally use `static inline` functions in header files (Andres Freund)
  This may result in warnings and/or wasted code space with very old compilers, but the notational improvement seems worth it.

- Improve TAP testing infrastructure (Michael Paquier, Craig Ringer, Álvaro Herrera, Stephen Frost)
  Notably, it is now possible to test recovery scenarios using this infrastructure.

- Make `trace_lwlocks` identify individual locks by name (Robert Haas)

- Improve `psql`’s tab-completion code infrastructure (Thomas Munro, Michael Paquier)
  Tab-completion rules are now considerably easier to write, and more compact.

- Nail the `pg_shseclabel` system catalog into cache, so that it is available for access during connection authentication (Adam Brightwell)
  The core code does not use this catalog for authentication, but extensions might wish to consult it.

- Restructure index access method API to hide most of it at the C level (Alexander Korotkov, Andrew Gierth)
  This change modernizes the index AM API to look more like the designs we have adopted for foreign data wrappers and tablesample handlers. This simplifies the C code and makes it much more practical to define index access methods in installable extensions. A consequence is that most of the columns of the `pg_am` system catalog have disappeared. New inspection functions have been added to allow SQL queries to determine index AM properties that used to be discoverable from `pg_am`.

- Add `pg_init_privs` system catalog to hold original privileges of initdb-created and extension-created objects (Stephen Frost)
  This infrastructure allows `pg_dump` to dump changes that an installation may have made in privileges attached to system objects. Formerly, such changes would be lost in a dump and reload, but now they are preserved.

- Change the way that extensions allocate custom `LWLocks` (Amit Kapila, Robert Haas)
  The `RequestAddinLWLocks()` function is removed, and replaced by `RequestNamedLWLockTranche()`. This allows better identification of custom `LWLocks`, and is less error-prone.

- Improve the isolation tester to allow multiple sessions to wait concurrently, allowing testing of deadlock scenarios (Robert Haas)

- Introduce extensible node types (KaiGai Kohei)
  This change allows FDWs or custom scan providers to store data in a plan tree in a more convenient format than was previously possible.

- Make the planner deal with post-scan/join query steps by generating and comparing `Paths`, replacing a lot of ad-hoc logic (Tom Lane)
  This change provides only marginal user-visible improvements today, but it enables future work on a lot of upper-planner improvements that were impractical to tackle using the old code structure.

- Support partial aggregation (David Rowley, Simon Riggs)
This change allows the computation of an aggregate function to be split into separate parts, for example so that parallel worker processes can cooperate on computing an aggregate. In future it might allow aggregation across local and remote data to occur partially on the remote end.

- Add a generic command progress reporting facility (Vinayak Pokale, Rahila Syed, Amit Langote, Robert Haas)
- Separate out psql’s flex lexer to make it usable by other client programs (Tom Lane, Kyotaro Horiguchi)

This eliminates code duplication for programs that need to be able to parse SQL commands well enough to identify command boundaries. Doing that in full generality is more painful than one could wish, and up to now only psql has really gotten it right among our supported client programs.

A new source-code subdirectory src/fe_utils/ has been created to hold this and other code that is shared across our client programs. Formerly such sharing was accomplished by symbolic linking or copying source files at build time, which was ugly and required duplicate compilation.

- Introduce `WaitEventSet` API to allow efficient waiting for event sets that usually do not change from one wait to the next (Andres Freund, Amit Kapila)
- Add a generic interface for writing WAL records (Alexander Korotkov, Petr Jelínek, Markus Nullmeier)

This change allows extensions to write WAL records for changes to pages using a standard layout. The problem of needing to replay WAL without access to the extension is solved by having generic replay code. This allows extensions to implement, for example, index access methods and have WAL support for them.

- Support generic WAL messages for logical decoding (Petr Jelínek, Andres Freund)

This feature allows extensions to insert data into the WAL stream that can be read by logical-decoding plugins, but is not connected to physical data restoration.

- Allow SP-GiST operator classes to store an arbitrary “traversal value” while descending the index (Alexander Lebedev, Teodor Sigaev)

This is somewhat like the “reconstructed value”, but it could be any arbitrary chunk of data, not necessarily of the same data type as the indexed column.

- Introduce a `LOG_SERVER_ONLY` message level for `ereport()` (David Steele)

This level acts like `LOG` except that the message is never sent to the client. It is meant for use in auditing and similar applications.

- Provide a `Makefile` target to build all generated headers (Michael Paquier, Tom Lane)

`submake-generated-headers` can now be invoked to ensure that generated backend header files are up-to-date. This is useful in subdirectories that might be built “standalone”.

- Support OpenSSL 1.1.0 (Andreas Karlsson, Heikki Linnakangas)

### E.14.3.13. Additional Modules

- Add configuration parameter `auto_explain.sample_rate` to allow `contrib/auto_explain` to capture just a configurable fraction of all queries (Craig Ringer, Julien Rouhaud)

This allows reduction of overhead for heavy query traffic, while still getting useful information on average.
• Add contrib/bloom module that implements an index access method based on Bloom filtering (Teodor Sigaev, Alexander Korotkov)

  This is primarily a proof-of-concept for non-core index access methods, but it could be useful in its own right for queries that search many columns.

• In contrib/cube, introduce distance operators for cubes, and support kNN-style searches in GiST indexes on cube columns (Stas Kelvich)

• Make contrib/hstore’s hstore_to_jsonb_loose() and hstore_to_json_loose() functions agree on what is a number (Tom Lane)

  Previously, hstore_to_jsonb_loose() would convert numeric-looking strings to JSON numbers, rather than strings, even if they did not exactly match the JSON syntax specification for numbers. This was inconsistent with hstore_to_json_loose(), so tighten the test to match the JSON syntax.

• Add selectivity estimation functions for contrib/intarray operators to improve plans for queries using those operators (Yury Zhuravlev, Alexander Korotkov)

• Make contrib/pageinspect’s heap_page_items() function show the raw data in each tuple, and add new functions tuple_data_split() and heap_page_item_attrs() for inspection of individual tuple fields (Nikolay Shaplov)

• Add an optional S2K iteration count parameter to contrib/pgcrypto’s pgp_sym_encrypt() function (Jeff Janes)

• Add support for “word similarity” to contrib/pg_trgm (Alexander Korotkov, Artur Zakirov)

  These functions and operators measure the similarity between one string and the most similar single word of another string.

• Add configuration parameter pg_trgm.similarity_threshold for contrib/pg_trgm’s similarity threshold (Artur Zakirov)

  This threshold has always been configurable, but formerly it was controlled by special-purpose functions set_limit() and show_limit(). Those are now deprecated.

• Improve contrib/pg_trgm’s GIN operator class to speed up index searches in which both common and rare keys appear (Jeff Janes)

• Improve performance of similarity searches in contrib/pg_trgm GIN indexes (Christophe Fornaroli)

• Add contrib/pg_visibility module to allow examining table visibility maps (Robert Haas)

• Add ssl_extension_info() function to contrib/sslinfo, to print information about SSL extensions present in the X509 certificate used for the current connection (Dmitry Voronin)

E.14.3.13.1. postgres_fdw

• Allow extension-provided operators and functions to be sent for remote execution, if the extension is whitelisted in the foreign server’s options (Paul Ramsey)

  Users can enable this feature when the extension is known to exist in a compatible version in the remote database. It allows more efficient execution of queries involving extension operators.

• Consider performing sorts on the remote server (Ashutosh Bapat)

• Consider performing joins on the remote server (Shigeru Hanada, Ashutosh Bapat)

• When feasible, perform UPDATE or DELETE entirely on the remote server (Etsuro Fujita)
Formerly, remote updates involved sending a `SELECT FOR UPDATE` command and then updating or deleting the selected rows one-by-one. While that is still necessary if the operation requires any local processing, it can now be done remotely if all elements of the query are safe to send to the remote server.

- Allow the fetch size to be set as a server or table option (Corey Huinker)
  
  Formerly, `postgres_fdw` always fetched 100 rows at a time from remote queries; now that behavior is configurable.

- Use a single foreign-server connection for local user IDs that all map to the same remote user (Ashutosh Bapat)

- Transmit query cancellation requests to the remote server (Michael Paquier, Etsuro Fujita)
  
  Previously, a local query cancellation request did not cause an already-sent remote query to terminate early.

---

**E.15. Prior Releases**

Release notes for prior release branches can be found at https://www.postgresql.org/docs/release/
Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core PostgreSQL system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers extensions and other server plug-in modules found in contrib. Appendix G covers utility programs.

When building from the source distribution, these components are not built automatically, unless you build the "world" target (see step 2). You can build and install all of them by running:

```
make
make install
```

in the contrib directory of a configured source tree; or to build and install just one selected module, do the same in that module’s subdirectory. Many of the modules have regression tests, which can be executed by running:

```
make check
```

before installation or

```
make installcheck
```

once you have a PostgreSQL server running.

If you are using a pre-packaged version of PostgreSQL, these modules are typically made available as a separate subpackage, such as postgresql-contrib.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. In PostgreSQL 9.1 and later, this is done by executing a CREATE EXTENSION command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command must be run by a database superuser. This registers the new SQL objects in the current database only, so you need to run this command in each database that you want the module’s facilities to be available in. Alternatively, run it in database template1 so that the extension will be copied into subsequently-created databases by default.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the CREATE EXTENSION command. By default, the objects will be placed in your current creation target schema, which in turn defaults to public.

If your database was brought forward by dump and reload from a pre-9.1 version of PostgreSQL, and you had been using the pre-9.1 version of the module in it, you should instead do

```
CREATE EXTENSION module_name FROM unpackaged;
```
This will update the pre-9.1 objects of the module into a proper extension object. Future updates to the module will be managed by ALTER EXTENSION. For more information about extension updates, see Section 36.15.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of shared_preload_libraries. See the documentation of each module for details.

F.1. adminpack

adminpack provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is restricted to superusers.

The functions shown in Table F-1 provide write access to files on the machine hosting the server. (See also the functions in Table 9-86, which provide read-only access.) Only files within the database cluster directory can be accessed, but either a relative or absolute path is allowable.

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_catalog.pg_file_write(filename text, data text, append boolean)</td>
<td>bigint</td>
<td>Write, or append to, a text file</td>
</tr>
<tr>
<td>pg_catalog.pg_file_rename(oldname text, newname text [, archivename text])</td>
<td>boolean</td>
<td>Rename a file</td>
</tr>
<tr>
<td>pg_catalog.pg_file_unlink(filename text)</td>
<td>boolean</td>
<td>Remove a file</td>
</tr>
<tr>
<td>pg_catalog.pg_logdir_ls()</td>
<td>setof record</td>
<td>List the log files in the log_directory directory</td>
</tr>
</tbody>
</table>

pg_file_write writes the specified data into the file named by filename. If append is false, the file must not already exist. If append is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

pg_file_rename renames a file. If archivename is omitted or NULL, it simply renames oldname to newname (which must not already exist). If archivename is provided, it first renames newname to archivename (which must not already exist), and then renames oldname to newname. In event of failure of the second rename step, it will try to rename archivename back to newname before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

pg_file_unlink removes the specified file. Returns true on success, false if the specified file is not present or the unlink() call fails; other cases throw errors.

pg_logdir_ls returns the start timestamps and path names of all the log files in the log_directory directory. The log_filename parameter must have its default setting (postgresql-%Y-%m-%d_%H%M%S.log) to use this function.

The functions shown in Table F-2 are deprecated and should not be used in new applications; instead use those shown in Table 9-77 and Table 9-86. These functions are provided in adminpack only for compatibility with old versions of pgAdmin.
Table F-2. Deprecated adminpack Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_catalog.pg_file_read(filename text, offset bigint, nbytes bigint)</td>
<td>text</td>
<td>Alternate name for pg_read_file()</td>
</tr>
<tr>
<td>pg_catalog.pg_file_length(filename text)</td>
<td>bigint</td>
<td>Same as size column returned by pg_stat_file()</td>
</tr>
<tr>
<td>pg_catalog.pg_logfile_rotate()</td>
<td>integer</td>
<td>Alternate name for pg_rotate_logfile(), but note that it returns integer 0 or 1 rather than boolean</td>
</tr>
</tbody>
</table>

F.2. auth_delay

auth_delay causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via shared_preload_libraries in postgresql.conf.

F.2.1. Configuration Parameters

auth_delay.milliseconds(int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = ‘auth_delay’
auth_delay.milliseconds = ‘500’
```

F.2.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.3. auto_explain

The auto_explain module provides a means for logging execution plans of slow statements automatically, without having to run EXPLAIN by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:
LOAD 'auto_explain';

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

**F.3.1. Configuration Parameters**

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

- `auto_explain.log_min_duration` (integer)
  
  `auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement’s plan to be logged. Setting this to zero logs all plans. Minus-one (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

- `auto_explain.log_analyze` (boolean)
  
  `auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

  **Note:** When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

- `auto_explain.log_buffers` (boolean)
  
  `auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it’s equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

- `auto_explain.log_timing` (boolean)
  
  `auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it’s equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

- `auto_explain.log_triggers` (boolean)
  
  `auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.
**Appendix F. Additional Supplied Modules**

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it’s equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```sql
# postgresql.conf
session_preload_libraries = 'auto_explain'
auto_explain.log_min_duration = '3s'
```

**F.3.2. Example**

```sql
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
     FROM pg_class, pg_index
     WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG: duration: 3.651 ms plan:
  Query Text: SELECT count(*)
     FROM pg_class, pg_index
     WHERE oid = indrelid AND indisunique;
Aggregate (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1 loops=1)
  ->  Hash Join (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92)
       Hash Cond: (pg_class.oid = pg_index.indrelid)
       ->  Seq Scan on pg_class (cost=0.00..9.55 rows=255 width=4) (actual time=0.016..0.140 rows=255 loops=1)
       ->  Hash (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92)
           Buckets: 1024 Batches: 1 Memory Usage: 4kB
  Filter: indisunique
```

2337
F.4. bloom

*bloom* provides an index access method based on Bloom filters.\(^1\)

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.4.1. Parameters

A *bloom* index accepts the following parameters in its *WITH* clause:

- **length**
  
  Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

- **col1 -- col32**
  
  Number of bits generated for each index column. Each parameter’s name refers to the number of the index column that it controls. The default is 2 bits and maximum is 4095. Parameters for index columns not actually used are ignored.

F.4.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)  
  WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes i1 and i2 mapped to 2 bits, and attribute i3 mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

---

Appendix F: Additional Supplied Modules

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```sql
# CREATE TABLE tbloom AS
    SELECT
        (random() * 1000000)::int as i1,
        (random() * 1000000)::int as i2,
        (random() * 1000000)::int as i3,
        (random() * 1000000)::int as i4,
        (random() * 1000000)::int as i5,
        (random() * 1000000)::int as i6
    FROM
        generate_series(1,10000000);
SELECT 10000000
# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
----------------
153 MB
(1 row)
# CREATE index btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
----------------
387 MB
(1 row)

A sequential scan over this large table takes a long time:

```sql
# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
 QUERY PLAN
------------------------------------------------------------------------------------------------------------
Seq Scan on tbloom (cost=0.00..213694.08 rows=1 width=24) (actual time=1445.438..1445.438 rows=0 loops=1)
FILTER: ((i2 = 898732) AND (i5 = 123451))
Heap Fetches: 0
Planning time: 0.177 ms
Execution time: 1445.473 ms
(5 rows)

So the planner will usually select an index scan if possible. With a btree index, we get results like this:

```sql
# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
 QUERY PLAN
--------------------------------------------------------------------------------------------------------------------------------
Index Only Scan using btreeidx on tbloom (cost=0.56..298311.96 rows=1 width=24) (actual time=445.709..445.709 rows=0 loops=1)
Index Cond: ((i2 = 898732) AND (i5 = 123451))
Heap Fetches: 0
Planning time: 0.193 ms
Execution time: 445.770 ms
(5 rows)
```
Bloom is better than btree in handling this type of search:

```sql
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

**QUERY PLAN**

```
---------------------------------------------------------------------------------------------------------------------------
Bitmap Heap Scan on tbloom (cost=178435.39..178439.41 rows=1 width=24) (actual time=76.698..76.698 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 2439
  Heap Blocks: exact=2408
  -> Bitmap Index Scan on bloomidx (cost=0.00..178435.39 rows=1 width=0) (actual time=72.455..72.455 rows=2439 loops=1)
    Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning time: 0.475 ms
Execution time: 76.778 ms
(8 rows)
```

Note the relatively large number of false positives: 2439 rows were selected to be visited in the heap, but none actually matched the query. We could reduce that by specifying a larger signature length. In this example, creating the index with `length=200` reduced the number of false positives to 55; but it doubled the index size (to 306 MB) and ended up being slower for this query (125 ms overall).

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```sql
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
```

**QUERY PLAN**

```
------------------------------------------------------------------------------------------------------------------------------
Bitmap Heap Scan on tbloom (cost=9.29..13.30 rows=1 width=24) (actual time=0.148..0.148 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  -> BitmapAnd (cost=9.29..9.29 rows=1 width=0) (actual time=0.145..0.145 rows=0 loops=1)
    -> Bitmap Index Scan on tbloom_i5_idx (cost=0.00..4.52 rows=11 width=0) (actual time=0.089..0.089 rows=10 loops=1)
      Index Cond: (i5 = 123451)
    -> Bitmap Index Scan on tbloom_i2_idx (cost=0.00..4.52 rows=11 width=0) (actual time=0.048..0.048 rows=8 loops=1)
      Index Cond: (i2 = 898732)
Planning time: 2.049 ms
Execution time: 0.280 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a large penalty in index size. Each of the single-column btree indexes occupies 214 MB, so the total space needed is over 1.2GB, more than 8 times the space used by the bloom index.

**F.4.3. Operator Class Interface**

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the text data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
  OPERATOR 1 =(text, text),
  FUNCTION 1 hashtext(text);
```
Appendix F. Additional Supplied Modules

F.4.4. Limitations

• Only operator classes for int4 and text are included with the module.
• Only the − operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
• bloom access method doesn’t support UNIQUE indexes.
• bloom access method doesn’t support searching for NULL values.

F.4.5. Authors
Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia
Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia
Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.5. btree_gin

btree_gin provides sample GIN operator classes that implement B-tree equivalent behavior for the data types int2, int4, int8, float4, float8, timestamp with time zone, timestamp without time zone, time with time zone, time without time zone, date, interval, oid, money, "char", varchar, text, bytea, bit, varbit, macaddr, inet, and cidr.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

F.5.1. Example Usage

CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;

F.5.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin for additional information.
F.6. btree_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp` with time zone, `timestamp` without time zone, `time` with time zone, `time` without time zone, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `inet`, and `cidr`.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolon GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` ("not equals"). This may be useful in combination with an exclusion constraint, as described below. Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp` with time zone, `timestamp` without time zone, `time` without time zone, `date`, `interval`, `oid`, and `money`.

F.6.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <--> 42 AS dist FROM test ORDER BY a <--> 42 LIMIT 10;
```

Use an exclusion constraint to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (  
  cage INTEGER,  
  animal TEXT,  
  EXCLUDE USING GIST (cage WITH =, animal WITH <>) 
);

=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 1 1  
=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 1 1  
=> INSERT INTO zoo VALUES(123, 'lion');  
ERROR: conflicting key value violates exclusion constraint "zoo_cage_animal_excl"  
DETAIL: Key (cage, animal)=(123, lion) conflicts with existing key (cage, animal)=(123,  
=> INSERT INTO zoo VALUES(124, 'lion');  
INSERT 1 1
```
F.6.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), and Janko Richter (<jankorichter@yahoo.de>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information.

F.7. chkpass

This module implements a data type `chkpass` that is designed for storing encrypted passwords. Each password is automatically converted to encrypted form upon entry, and is always stored encrypted. To compare, simply compare against a clear text password and the comparison function will encrypt it before comparing.

There are provisions in the code to report an error if the password is determined to be easily crackable. However, this is currently just a stub that does nothing.

If you precede an input string with a colon, it is assumed to be an already-encrypted password, and is stored without further encryption. This allows entry of previously-encrypted passwords.

On output, a colon is prepended. This makes it possible to dump and reload passwords without re-encrypting them. If you want the encrypted password without the colon then use the `raw()` function. This allows you to use the type with things like Apache’s `Auth_PostgreSQL` module.

The encryption uses the standard Unix function `crypt()`, and so it suffers from all the usual limitations of that function; notably that only the first eight characters of a password are considered.

Note that the `chkpass` data type is not indexable.

Sample usage:

```sql
test=# create table test (p chkpass);
CREATE TABLE

test=# insert into test values ('hello');
INSERT 0 1

test=# select * from test;
p
    ----------------
    :dVGkpXdOrE3ko
(1 row)

test=# select raw(p) from test;
raw
    ----------------
    dVGkpXdOrE3ko
(1 row)

test=# select p = 'hello' from test;
?column?
    -----------
    t
(1 row)

test=# select p = 'goodbye' from test;
?column?
    -----------
f
```
F.7.1. Author

D’Arcy J.M. Cain (<darcy@druid.net>)

F.8. citext

The citext module provides a case-insensitive character string type, citext. Essentially, it internally calls lower when comparing values. Otherwise, it behaves almost exactly like text.

F.8.1. Rationale

The standard approach to doing case-insensitive matches in PostgreSQL has been to use the lower function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use lower on both the column and the query value.
- It won’t use an index, unless you create a functional index using lower.
- If you declare a column as UNIQUE or PRIMARY KEY, the implicitly generated index is case-sensitive. So it’s useless for case-insensitive searches, and it won’t enforce uniqueness case-insensitively.

The citext data type allows you to eliminate calls to lower in SQL queries, and allows a primary key to be case-insensitive. citext is locale-aware, just like text, which means that the matching of upper case and lower case characters is dependent on the rules of the database’s LC_CTYPE setting. Again, this behavior is identical to the use of lower in queries. But because it’s done transparently by the data type, you don’t have to remember to do anything special in your queries.

F.8.2. How to Use It

Here’s a simple example of usage:

```
CREATE TABLE users (  
nick CITEXT PRIMARY KEY,  
  pass TEXT NOT NULL
);
```

```
INSERT INTO users VALUES ( 'larry', md5(random()::text) );
INSERT INTO users VALUES ( 'Tom', md5(random()::text) );
INSERT INTO users VALUES ( 'Damian', md5(random()::text) );
INSERT INTO users VALUES ( 'NEAL', md5(random()::text) );
INSERT INTO users VALUES ( 'Bjørn', md5(random()::text) );
```
SELECT * FROM users WHERE nick = 'Larry';

The select statement will return one tuple, even though the nick column was set to larry and the query was for Larry.

F.8.3. String Comparison Behavior

citext performs comparisons by converting each string to lower case (as though lower were called) and then comparing the results normally. Thus, for example, two strings are considered equal if lower would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are citext-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators ~ and ~* exhibit the same behavior when applied to citext: they both match case-insensitively. The same is true for !~ and !~*, as well as for the LIKE operators ~~ and ~~~, and !$~ and !$~*. If you’d like to match case-sensitively, you can cast the operator’s arguments to text.

Similarly, all of the following functions perform matching case-insensitively if their arguments are citext:

- regexp_matches()
- regexp_replace()
- regexp_split_to_array()
- regexp_split_to_table()
- replace()
- split_part()
- strpos()
- translate()

For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to text before using one of these functions if you want case-sensitive behavior.

F.8.4. Limitations

- citext’s case-folding behavior depends on the LC_CTYPE setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you’re happy with your collation, you should be happy with citext’s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.

- As of PostgreSQL 9.1, you can attach a COLLATE specification to citext columns or data values. Currently, citext operators will honor a non-default COLLATE specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database’s LC_CTYPE setting (that is, as though COLLATE "default" were given). This may be changed in a future release so that both steps follow the input COLLATE specification.
Appendix F. Additional Supplied Modules

- citext is not as efficient as text because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. It is, however, slightly more efficient than using lower to get case-insensitive matching.

- citext doesn’t help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the text type and manually use the lower function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as citext and explicitly casting the column to text when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the citext operators must be in the current search_path (typically public); if it is not, the normal case-sensitive text operators will be invoked instead.

F.8.5. Author

David E. Wheeler <david@kineticode.com>

Inspired by the original citext module by Donald Fraser.

F.9. cube

This module implements a data type cube for representing multidimensional cubes.

F.9.1. Syntax

Table F-3 shows the valid external representations for the cube type. x, y, etc. denote floating-point numbers.

Table F-3. Cube External Representations

<table>
<thead>
<tr>
<th>External Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>A one-dimensional point (or, zero-length one-dimensional interval)</td>
</tr>
<tr>
<td>(x)</td>
<td>Same as above</td>
</tr>
<tr>
<td>x1,x2,...,xn</td>
<td>A point in n-dimensional space, represented internally as a zero-volume cube</td>
</tr>
<tr>
<td>(x1,x2,...,xn)</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x), (y)</td>
<td>A one-dimensional interval starting at x and ending at y or vice versa; the order does not matter</td>
</tr>
<tr>
<td>[(x), (y)]</td>
<td>Same as above</td>
</tr>
<tr>
<td>(x1, ..., xn), (y1, ..., yn)</td>
<td>An n-dimensional cube represented by a pair of its diagonally opposite corners</td>
</tr>
<tr>
<td>[(x1, ..., xn), (y1, ..., yn)]</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

It does not matter which order the opposite corners of a cube are entered in. The cube functions auto-
matically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so \([x, y]\) is the same as \([ (x), (y) ]\).

### F.9.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

### F.9.3. Usage

Table F-4 shows the operators provided for type `cube`.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Result</th>
<th>Description</th>

<td>Chebyshev (L-inf metric) distance between a and b.</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators @> and @@ were respectively called @ and ~. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The scalar ordering operators (<, >, etc) do not make a lot of sense for any practical purpose but sorting. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for cube, which can be useful for example if you would like a UNIQUE constraint on a cube column.

The cube module also provides a GiST index operator class for cube values. A cube GiST index can be used to search for values using the -=, &&, @, and @@ operators in WHERE clauses.

In addition, a cube GiST index can be used to find nearest neighbors using the metric operators <>, <#>, and <= in ORDER BY clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <=> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The ~> operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F-5 shows the available functions.

Table F-5. Cube Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Result</th>
<th>Description</th>
<th>Example</th>
</tr>

</table>
### Appendix F: Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Result</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
</table>
| cube_subset(cube, integer[]) | cube   | Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired. | cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[2]) == '(3),(7)'
|                           |        | | cube_subset(cube('(1,3,5),(6,7,8)'), ARRAY[3,2,1,1]) == '(5,3,1,1),(8,7,6,6)'                                                                                                                             |                                                                                                                                       |
| cube_union(cube, cube)    | cube   | Produces the union of two cubes.                                                                                                                                                                         | cube_union(cube('(1,3,5),(6,7,8)'), cube('(3,4,5),(6,7,8)')) == '(1,3,5),(3,4,5),(6,7,8)'                                           |
| cube_inter(cube, cube)    | cube   | Produces the intersection of two cubes.                                                                                                                                                                  | cube_inter(cube('a,b,c'), cube('b,c,d')) == 'b,c'                                                                                     |
### Appendix F: Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Result</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cube_enlarge(cube, r double, n integer)</code></td>
<td>cube</td>
<td>Increases the size of the cube by the specified radius r in at least n dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius r. Lower-left coordinates are decreased by r and upper-right coordinates are increased by r. If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when r &lt; 0) than both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged (r &gt; 0), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.</td>
<td>`cube_enlarge('1,2),(3,4)', 0.5, 3) == '0.5,1.5,-0.5),(3.5,4.5,0.5)'</td>
</tr>
</tbody>
</table>

### F.9.4. Defaults

I believe this union:

```sql
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-------------------
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```sql
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
```

2351
In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i.e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)','(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)','(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-------------------
t(1 row)
```

F.9.5. Notes

For examples of usage, see the regression test sql/cube.sql.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in cubedata.h if you need something bigger.

F.9.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include cube(float8[], float8[]) and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.
F.10. dblink

dblink is a module that supports connections to other PostgreSQL databases from within a database session.

See also postgres_fdw, which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

Name
dblink_connect — opens a persistent connection to a remote database

Synopsis
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text

Description
dblink_connect() establishes a connection to a remote PostgreSQL database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper dblink_fdw when defining the foreign server. See the example below, as well as CREATE SERVER and CREATE USER MAPPING.

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypassword options=--+search_path=. For details see Section 32.1.1. Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).
Notes

If untrusted users have access to a database that has not adopted a secure schema usage pattern, begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to `connstr`. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
```

```
dblink_connect
----------------
OK
(1 row)
```

```sql
SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```
dblink_connect
----------------
OK
(1 row)
```

```sql
-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work properly
-- Otherwise, you will receive the following error from dblink_connect():
-- ERROR: password is required
-- DETAIL: Non-superuser cannot connect if the server does not request a password
-- HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1', dbname 'contrib_regression');
CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user 'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
```

```
dblink_connect
----------------
OK
(1 row)
```

```sql
SELECT * FROM dblink('myconn','fdtest') AS t(a int, b text, c text[]);
```

```
a | b | c
----+---+-----------------
0 | a | {a0,b0,c0}
1 | b | {a1,b1,c1}
2 | c | {a2,b2,c2}
```
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;

3 | d | (a3,b3,c3)
4 | e | (a4,b4,c4)

7 | h | (a7,b7,c7)
8 | i | (a8,b8,c8)
9 | j | (a9,b9,c9)
10 | k | (a10,b10,c10)
(11 rows)
dblink_connect_u

Name
dblink_connect_u — opens a persistent connection to a remote database, insecurely

Synopsis
dblink_connect_u(text connstr) returns text
dblink_connect_u(text connname, text connstr) returns text

Description
dblink_connect_u() is identical to dblink_connect(), except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local PostgreSQL server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a ~/.pgpass file belonging to the server’s user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, dblink_connect_u() is initially installed with all privileges revoked from PUBLIC, making it un-callable except by superusers. In some situations it may be appropriate to grant EXECUTE permission for dblink_connect_u() to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any ~/.pgpass file belonging to the server’s user not contain any records specifying a wildcard host name.

For further details see dblink_connect().

2356
**dblink_disconnect**

**Name**  
dblink_disconnect — closes a persistent connection to a remote database

**Synopsis**  
dblink_disconnect() returns text  
dblink_disconnect(text connname) returns text

**Description**  
dblink_disconnect() closes a connection previously opened by dblink_connect(). The form with no arguments closes an unnamed connection.

**Arguments**  

connname  
The name of a named connection to be closed.

**Return Value**  
Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

**Examples**  

```sql  
SELECT dblink_disconnect();  
dblink_disconnect  
-------------------  
OK  
(1 row)  

SELECT dblink_disconnect('myconn');  
dblink_disconnect  
-------------------  
OK  
(1 row)  
```
**Name**

dblink — executes a query in a remote database

**Synopsis**

dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record

**Description**

dblink executes a query (usually a SELECT, but it can be any SQL statement that returns rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

**Arguments**

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for dblink_connect.

sql

The SQL query that you wish to execute in the remote database, for example select * from foo.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) produced by the query. Since dblink can be used with any query, it is declared to return record, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise PostgreSQL would not know what to expect. Here is an example:

```sql
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
```
The “alias” part of the FROM clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a PostgreSQL extension.) This allows the system to understand what * should expand to, and what pronoame in the WHERE clause refers to, in advance of trying to execute the function. At runtime, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the FROM clause. The column names need not match, however, and dblink does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the FROM clause.

**Notes**

A convenient way to use dblink with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```sql
CREATE VIEW myremote_pg_proc AS
    SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=','
    select pronoame, prosrc from pg_proc')
    AS t1(pronoame name, prosrc text);
```

```sql
SELECT * FROM myremote_pg_proc WHERE pronoame LIKE 'bytea%';
```

**Examples**

```sql
SELECT * FROM dblink('dbname=postgres options=-csearch_path=','
    select pronoame, prosrc from pg_proc')
    AS t1(pronoame name, prosrc text) WHERE pronoame LIKE 'bytea%';
```

**dblink_exec**

**Name**

dblink_exec — executes a command in a remote database

**Synopsis**

dblink_exec(text connname, text sql [, bool fail_on_error]) returns text  
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text  
dblink_exec(text sql [, bool fail_on_error]) returns text

**Description**

dblink_exec executes a command (that is, any SQL statement that doesn’t return rows) in a remote database.

When two text arguments are given, the first one is first looked up as a persistent connection’s name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for dblink_connect, and the indicated connection is made just for the duration of this command.

**Arguments**

**connname**

Name of the connection to use; omit this parameter to use the unnamed connection.

**connstr**

A connection info string, as previously described for dblink_connect.

**sql**

The SQL command that you wish to execute in the remote database, for example `insert into foo values(0,'a',"a0","b0","c0")`.

**fail_on_error**

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to ERROR.

**Return Value**

Returns status, either the command’s status string or ERROR.

**Examples**

SELECT dblink_connect(‘dbname=dlbink_test_standby’);
dblink_connect
-----------------
OK
(1 row)

SELECT dblink_exec('insert into foo values(21,"z","{"a0","b0","c0"}");');
  dblink_exec
-----------------
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
  dblink_connect
-----------------
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21,"z","{"a0","b0","c0"}");');
  dblink_exec
-----------------
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values ("foo"),false);
NOTICE: sql error
DETAIL:  ERROR: null value in column "relnamespace" violates not-null constraint
  dblink_exec
-----------------
ERROR
(1 row)
dblink_open

Name
dblink_open — opens a cursor in a remote database

Synopsis
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns text

Description
dblink_open() opens a cursor in a remote database. The cursor can subsequently be manipulated with \texttt{dblink\_fetch()} and \texttt{dblink\_close()}.

Arguments

\texttt{connname}

Name of the connection to use; omit this parameter to use the unnamed connection.

\texttt{cursorname}

The name to assign to this cursor.

\texttt{sql}

The \texttt{SELECT} statement that you wish to execute in the remote database, for example \texttt{select * from pg\_class}.

\texttt{fail\_on\_error}

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NO\-TICE, and the function’s return value is set to \texttt{ERROR}.

Return Value

Returns status, either \texttt{OK} or \texttt{ERROR}.

Notes

Since a cursor can only persist within a transaction, \texttt{dblink\_open} starts an explicit transaction block (\texttt{BEGIN}) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching \texttt{dblink\_close} is executed. Note that if you use \texttt{dblink\_exec} to change data between \texttt{dblink\_open} and \texttt{dblink\_close}, and then an error occurs or you use \texttt{dblink\_disconnect} before \texttt{dblink\_close}, your change will be lost because the transaction will be aborted.
**Examples**

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
  dblink_connect
-----------
  OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
-----------
  OK
(1 row)
```
**dblink_fetch**

**Name**

dblink_fetch — returns rows from an open cursor in a remote database

**Synopsis**

dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record

dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error]) returns setof record

**Description**

dblink_fetch fetches rows from a cursor previously established by dblink_open.

**Arguments**

conname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next howmany rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

**Return Value**

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for dblink.

**Notes**

On a mismatch between the number of return columns specified in the FROM clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote FETCH has been done.
Examples

SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
------------------
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like "bytea"');
dblink_open
-------------
OK
(1 row)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
----------+----------
byteacat | byteacat
byteacmp | byteacmp
byteaeq | byteaeq
byteage | byteage
byteagt | byteagt
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
----------+----------
byteain | byteain
byteale | byteale
bytealike | bytealike
bytealt | bytealt
byteane | byteane
(5 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
----------+--------
byteanlike | byteanlike
byteaout | byteaout
(2 rows)

SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
funcname | source
----------+--------
(0 rows)
**dblink_close**

**Name**

`dblink_close` — closes a cursor in a remote database

**Synopsis**

```sql
dblink_close(text cursorname [, bool fail_on_error]) returns text
```

**Description**

`dblink_close` closes a cursor previously opened with `dblink_open`.

**Arguments**

- **connname**
  
  Name of the connection to use; omit this parameter to use the unnamed connection.

- **cursorname**
  
  The name of the cursor to close.

- **fail_on_error**
  
  If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function’s return value is set to `ERROR`.

**Return Value**

Returns status, either `OK` or `ERROR`.

**Notes**

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

**Examples**

```sql
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
```

```
dblink_connect
-------------
OK
(1 row)
```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
  dblink_open
------------
   OK
(1 row)

SELECT dblink_close('foo');
  dblink_close
------------
   OK
(1 row)
dblink_get_connections

Name
dblink_get_connections — returns the names of all open named dblink connections

Synopsis
dblink_get_connections() returns text[]

Description
dblink_get_connections returns an array of the names of all open named dblink connections.

Return Value
Returns a text array of connection names, or NULL if none.

Examples
SELECT dblink_get_connections();
**dblink_error_message**

**Name**

`dblink_error_message` — gets last error message on the named connection

**Synopsis**

`dblink_error_message(text connname) returns text`

**Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

**Arguments**

`connname`

Name of the connection to use.

**Return Value**

Returns last error message, or `OK` if there has been no error in this connection.

**Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server’s response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

**Examples**

```sql
SELECT dblink_error_message('dtest1');
```
**dblink_send_query**

**Name**

`dblink_send_query` — sends an async query to a remote database

**Synopsis**

`dblink_send_query(text connname, text sql) returns int`

**Description**

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

**Arguments**

- **connname**
  
  Name of the connection to use.

- **sql**
  
  The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

**Return Value**

Returns 1 if the query was successfully dispatched, 0 otherwise.

**Examples**

```sql
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```
**dblink_is_busy**

**Name**

`dblink_is_busy` — checks if connection is busy with an async query

**Synopsis**

`dblink_is_busy(text connname) returns int`

**Description**

`dblink_is_busy` tests whether an async query is in progress.

**Arguments**

`connname`

Name of the connection to check.

**Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

**Examples**

```
SELECT dblink_is_busy('dtest1');
```
**dblink_get_notify**

**Name**

dblink_get_notify — retrieve async notifications on a connection

**Synopsis**

dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra text)

**Description**

dblink_get_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see LISTEN and NOTIFY.

**Arguments**

connname

The name of a named connection to get notifications on.

**Return Value**

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

**Examples**

```sql
SELECT dblink_exec('LISTEN virtual');

--

LISTEN
(1 row)

SELECT * FROM dblink_get_notify();

--

<table>
<thead>
<tr>
<th>notify_name</th>
<th>be_pid</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| (0 rows)

NOTIFY virtual;

NOTIFY

SELECT * FROM dblink_get_notify();

--

<table>
<thead>
<tr>
<th>notify_name</th>
<th>be_pid</th>
<th>extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>virtual</td>
<td>1229</td>
<td></td>
</tr>
</tbody>
</table>
| (1 row)     
```
dblink_get_result

Name
dblink_get_result — gets an async query result

Synopsis
dblink_get_result(text connname [, bool fail_on_error]) returns setof record

Description
dblink_get_result collects the results of an asynchronous query previously sent with
dblink_send_query. If the query is not already completed, dblink_get_result will wait until
it is.

Arguments
cconnname
   Name of the connection to use.
fail_on_error
   If true (the default when omitted) then an error thrown on the remote side of the connection
   causes an error to also be thrown locally. If false, the remote error is locally reported as a NO-
   TICE, and the function returns no rows.

Return Value
For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced
by the query. To use this function, you will need to specify the expected set of columns, as previously
discussed for dblink.

For an async command (that is, a SQL statement not returning rows), the function returns a single row
with a single text column containing the command’s status string. It is still necessary to specify that
the result will have a single text column in the calling FROM clause.

Notes
This function must be called if dblink_send_query returned 1. It must be called once for each
query sent, and one additional time to obtain an empty set result, before the connection can be used
again.

When using dblink_send_query and dblink_get_result, dblink fetches the entire remote
query result before returning any of it to the local query processor. If the query returns a large number
of rows, this can result in transient memory bloat in the local session. It may be better to open such
adblink_get_result

a query as a cursor with adblink_open and then fetch a manageable number of rows at a time. Alternatively, use plain adblink(), which avoids memory bloat by spooling large result sets to disk.

Examples

contrib_regression=# SELECT adblink_connect('dtest1', 'dbname=contrib_regression');
adblink_connect
----------------
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression=# adblink_send_query('dtest1', 'select * from foo where f1 < 3') AS t1;

| t1 |

contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text, f3 text) 
  f1 | f2 | f3 
----+----+----
(0 rows)
**dblink_cancel_query**

**Name**

dblink_cancel_query — cancels any active query on the named connection

**Synopsis**

dblink_cancel_query(text connname) returns text

**Description**

dblink_cancel_query attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling dblink_get_result.

**Arguments**

connname

Name of the connection to use.

**Return Value**

Returns OK if the cancel request has been sent, or the text of an error message on failure.

**Examples**

SELECT dblink_cancel_query('dtest1');
**dblink_get_pkey**

**Name**

`dblink_get_pkey` — returns the positions and field names of a relation’s primary key fields

**Synopsis**

`dblink_get_pkey(text relname) returns setof dblink_pkey_results`

**Description**

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

**Arguments**

`relname`

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**Return Value**

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to `n`; it is the number of the field within the primary key, not the number within the table’s columns.

**Examples**

```sql
CREATE TABLE foobar (  
  f1 int,  
  f2 int,  
  f3 int,  
  PRIMARY KEY (f1, f2, f3)  
);
CREATE TABLE

SELECT * FROM dblink_get_pkey('foobar');

<table>
<thead>
<tr>
<th>position</th>
<th>colname</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>f1</td>
</tr>
<tr>
<td>2</td>
<td>f2</td>
</tr>
</tbody>
</table>
```
```
3 | f3
(3 rows)
```
**dblink_build_sql_insert**

**Name**

dblink_build_sql_insert — builds an INSERT statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_insert(text relname,
                       int2vector primary_key_attnums,
                       integer num_primary_key_atts,
                       text[] src_pk_att_vals_array,
                       text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_insert can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL INSERT command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

**Arguments**

* relname
  Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

* primary_key_attnums
  Attribute numbers (1-based) of the primary key fields, for example 1 2.

* num_primary_key_atts
  The number of primary key fields.

* src_pk_att_vals_array
  Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

* tgt_pk_att_vals_array
  Values of the primary key fields to be placed in the resulting INSERT command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.
Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```sql
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b""a"}');
```

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b"a','1')
```
(1 row)
**dblink_build_sql_delete**

**Name**

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

**Synopsis**

```plaintext
dblink_build_sql_delete(text relname,
                        int2vector primary_key_attnums,
                        integer num_primary_key_atts,
                        text[] tgt_pk_att_vals_array) returns text
```

**Description**

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL `DELETE` command that will delete the row with the given primary key values.

**Arguments**

- **relname**
  
  Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

- **primary_key_attnums**

  Attribute numbers (1-based) of the primary key fields, for example 1 2.

- **num_primary_key_atts**

  The number of primary key fields.

- **tgt_pk_att_vals_array**

  Values of the primary key fields to be used in the resulting `DELETE` command. Each field is represented in text form.

**Return Value**

Returns the requested SQL statement as text.

**Notes**

As of PostgreSQL 9.0, the attribute numbers in `primary_key_attnums` are interpreted as logical column numbers, corresponding to the column’s position in `SELECT * FROM relname`. Previous
versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

**Examples**

```sql
SELECT dblink_build_sql_delete(""MyFoo"", '1 2', 2, '{"1", "b"}');
```

```
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'
(1 row)
```
**dblink_build_sql_update**

**Name**

dblink_build_sql_update — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

**Synopsis**

dblink_build_sql_update(text relname,
    int2vector primary_key_attnums,
    integer num_primary_key_atts,
    text[] src_pk_att_vals_array,
    text[] tgt_pk_att_vals_array) returns text

**Description**

dblink_build_sql_update can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and dblink_build_sql_insert is that it’s assumed that the target row already exists in the remote table.

**Arguments**

**relname**

Name of a local relation, for example foo or myschema.mytab. Include double quotes if the name is mixed-case or contains special characters, for example "FooBar"; without quotes, the string will be folded to lower case.

**primary_key_attnums**

Attribute numbers (1-based) of the primary key fields, for example 1 2.

**num_primary_key_atts**

The number of primary key fields.

**src_pk_att_vals_array**

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

**tgt_pk_att_vals_array**

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.
Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in primary_key_attnums are interpreted as logical column numbers, corresponding to the column’s position in SELECT * FROM relname. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```sql
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');
```

```
UPDATE foo SET f1='1', f2='b', f3='1' WHERE f1='1' AND f2='b'
(1 row)
```
F.11. dict_int

dict_int is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

F.11.1. Configuration

The dictionary accepts two options:

- The maxlen parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The rejectlong parameter specifies whether an overlength integer should be truncated or ignored. If rejectlong is false (the default), the dictionary returns the first maxlen digits of the integer. If rejectlong is true, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

F.11.2. Usage

Installing the dict_int extension creates a text search template intdict_template and a dictionary intdict based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
```

```
ts_lexize
--------
{123456}
```

but real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR int, uint WITH intdict;
```

F.12. dict_xsyn

dict_xsyn (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.
Appendix F. Additional Supplied Modules

F.12.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary’s output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary’s output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:
  ```plaintext
  word syn1 syn2 syn3
  ```
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

F.12.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```sql
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY

or create new dictionaries based on the template.

To test the dictionary, you can try

```sql
mydb=# SELECT ts_lexize('xsyn', 'word');
  ts_lexize
-----------
  {syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'word');
  ts_lexize
-----------
  {word,syn1,syn2,syn3}

mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false, MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY

mydb=# SELECT ts_lexize('xsyn', 'syn1');
```

2387
Appendix F. Additional Supplied Modules

---

```sql
ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true, MATCHORIG=false, KEEPSYNONYMS=false);
```

ALTER TEXT SEARCH DICTIONARY

```sql
SELECT ts_lexize('xsyn', 'syn1');
```

Real-world usage will involve including it in a text search configuration as described in Chapter 12. That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR word, asciword WITH xsyn, english_stem;
```

---

**F.13. earthdistance**

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module (which must be installed before `earthdistance` can be installed). The second one is based on the built-in point data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that’s too inaccurate for you, you might want to look at the PostGIS project.)

**F.13.1. Cube-based Earth Distances**

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/\pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in Table F-6.

---

Table F-6. Cube-based Earthdistance Functions

---

2. [http://postgis.net/](http://postgis.net/)
Appendix F: Additional Supplied Modules

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>earth()</td>
<td>float8</td>
<td>Returns the assumed radius of the Earth.</td>
</tr>
<tr>
<td>sec_to_gc(float8)</td>
<td>float8</td>
<td>Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.</td>
</tr>
<tr>
<td>gc_to_sec(float8)</td>
<td>float8</td>
<td>Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.</td>
</tr>
<tr>
<td>ll_to_earth(float8, float8)</td>
<td>earth</td>
<td>Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.</td>
</tr>
<tr>
<td>latitude(earth)</td>
<td>float8</td>
<td>Returns the latitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>longitude(earth)</td>
<td>float8</td>
<td>Returns the longitude in degrees of a point on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_distance(earth, earth)</td>
<td>float8</td>
<td>Returns the great circle distance between two points on the surface of the Earth.</td>
</tr>
<tr>
<td>earth_box(earth, float8)</td>
<td>cube</td>
<td>Returns a box suitable for an indexed search using the cube @&gt; operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using earth_distance should be included in the query.</td>
</tr>
</tbody>
</table>

F.13.2. Point-based Earth Distances

The second part of the module relies on representing Earth locations as values of type point, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in Table F-7.
Table F-7. Point-based Earthdistance Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>point &lt;@&gt; point</td>
<td>float8</td>
<td>Gives the distance in statute miles between two points on the Earth’s surface.</td>
</tr>
</tbody>
</table>

Note that unlike the cube-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The cube-based representation avoids these discontinuities.

**F.14. file_fdw**

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server’s file system. Data files must be in a format that can be read by `COPY FROM`; see `COPY` for details. Access to such data files is currently read-only.

A foreign table created using this wrapper can have the following options:

- **filename**
  Specifies the file to be read. Required. Must be an absolute path name.

- **format**
  Specifies the file’s format, the same as `COPY`’s `FORMAT` option.

- **header**
  Specifies whether the file has a header line, the same as `COPY`’s `HEADER` option.

- **delimiter**
  Specifies the file’s delimiter character, the same as `COPY`’s `DELIMITER` option.

- **quote**
  Specifies the file’s quote character, the same as `COPY`’s `QUOTE` option.

- **escape**
  Specifies the file’s escape character, the same as `COPY`’s `ESCAPE` option.

- **null**
  Specifies the file’s null string, the same as `COPY`’s `NULL` option.

- **encoding**
  Specifies the file’s encoding, the same as `COPY`’s `ENCODING` option.

Note that while `COPY` allows options such as OIDS and HEADER to be specified without a corresponding value, the foreign data wrapper syntax requires a value to be present in all cases. To activate `COPY` options normally supplied without a value, you can instead pass the value TRUE.

A column of a foreign table created using this wrapper can have the following options:
Appendix F. Additional Supplied Modules

force_not_null

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the file-level null option). This has the same effect as listing the column in COPY's FORCE_NOT_NULL option.

force_null

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as NULL even if the value is quoted. Without this option, only unquoted values matching the null string are returned as NULL. This has the same effect as listing the column in COPY's FORCE_NULL option.

COPY's OIDS and FORCE_QUOTE options are currently not supported by file_fdw.

These options can only be specified for a foreign table or its columns, not in the options of the file_fdw foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires superuser privileges, for security reasons: only a superuser should be able to determine which file is read. In principle non-superusers could be allowed to change the other options, but that's not supported at present.

For a foreign table using file_fdw, EXPLAIN shows the name of the file to be read. Unless COSTS OFF is specified, the file size (in bytes) is shown as well.

Example F-1. Create a Foreign Table for PostgreSQL CSV Logs

One of the obvious uses for the file_fdw is to make the PostgreSQL activity log available as a table for querying. To do this, first you must be logging to a CSV file, which here we will call pglog.csv. First, install file_fdw as an extension:

CREATE EXTENSION file_fdw;

Then create a foreign server:

CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;

Now you are ready to create the foreign data table. Using the CREATE FOREIGN TABLE command, you will need to define the columns for the table, the CSV file name, and its format:

CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,  
    hint text,  
    internal_query text,  
    internal_query_pos integer,  
    context text,  
    query text,  
    query_pos integer,
location text,
application_name text
) SERVER pglog
OPTIONS ( filename '/home/josh/9.1/data/pg_log/pglog.csv', format 'csv' );
That's it — now you can query your log directly. In production, of course, you would need to define
some way to deal with log rotation.

F.15. fuzzystrmatch

The fuzzystrmatch module provides several functions to determine similarities and distance be-
tween strings.

Caution
At present, the soundex, metaphone, dmetaphone, and dmetaphone_alt functions do not work well with multibyte encodings (such as UTF-8).

F.15.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same
code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is
not very useful for non-English names.

The fuzzystrmatch module provides two functions for working with Soundex codes:

soundex(text) returns text
difference(text, text) returns int

The soundex function converts a string to its Soundex code. The difference function converts
two strings to their Soundex codes and then reports the number of matching code positions. Since
Soundex codes have four characters, the result ranges from zero to four, with zero being no match
and four being an exact match. (Thus, the function is misnamed — similarity would have been a
better name.)

Here are some usage examples:

SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);
INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');

SELECT * FROM s WHERE soundex(nm) = soundex('john');
F.15.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

\[
\text{levenshtein} \left( \text{text source}, \text{text target}, \text{int ins_cost}, \text{int del_cost}, \text{int sub_cost} \right) \text{ returns int}
\]

\[
\text{levenshtein} \left( \text{text source}, \text{text target} \right) \text{ returns int}
\]

\[
\text{levenshtein_less_equal} \left( \text{text source}, \text{text target}, \text{int ins_cost}, \text{int del_cost}, \text{int sub_cost}, \text{int max_d} \right) \text{ returns int}
\]

\[
\text{levenshtein_less_equal} \left( \text{text source}, \text{text target}, \text{int max_d} \right) \text{ returns int}
\]

Both source and target can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
SELECT levenshtein('GUMBO', 'GAMBOL');
levenshtein
-------------
2
(1 row)

SELECT levenshtein('GUMBO', 'GAMBOL', 2,1,1);
levenshtein
-------------
3
(1 row)

SELECT levenshtein_less_equal('extensive', 'exhaustive',2);
levenshtein_less_equal
------------------------
3
(1 row)

SELECT levenshtein_less_equal('extensive', 'exhaustive',4);
levenshtein_less_equal
------------------------
4
(1 row)
```

F.15.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:
metaphone(text source, int max_output_length) returns text

source has to be a non-null string with a maximum of 255 characters. max_output_length sets
the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

test=# SELECT metaphone('GUMBO', 4);
metaphone
---------
KM
(1 row)

F.15.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a
“primary” and an “alternate”. In most cases they are the same, but for non-English names especially
they can be a bit different, depending on pronunciation. These functions compute the primary and
alternate codes:

dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text

There is no length limit on the input strings.

Example:

test=# select dmetaphone('gumbo');
dmetaphone
----------
KMP
(1 row)

F.16. hstore

This module implements the hstore data type for storing sets of key/value pairs within a single
PostgreSQL value. This can be useful in various scenarios, such as rows with many attributes that are
rarely examined, or semi-structured data. Keys and values are simply text strings.

F.16.1. hstore External Representation

The text representation of an hstore, used for input and output, includes zero or more key => value
pairs separated by commas. Some examples:

k => v
foo => bar, baz => whatever
"1-a" => "anything at all"

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between
pairs or around the => sign is ignored. Double-quote keys and values that include whitespace, com-
mas, <=s or =>s. To include a double quote or a backslash in a key or value, escape it with a backslash.
Each key in an hstore is unique. If you declare an hstore with duplicate keys, only one will be stored in the hstore and there is no guarantee as to which will be kept:

```sql
SELECT 'a=>'1,a=>'2'::hstore;
```

```bash
----------------
"a=>"1"
```

A value (but not a key) can be an SQL NULL. For example:

```sql
key => NULL
```

The NULL keyword is case-insensitive. Double-quote the NULL to treat it as the ordinary string “NULL”.

**Note:** Keep in mind that the hstore text format, when used for input, applies before any required quoting or escaping. If you are passing an hstore literal via a parameter, then no additional processing is needed. But if you’re passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the standard_conforming_strings configuration parameter) backslash characters need to be escaped correctly. See Section 4.1.2.1 for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it’s not strictly necessary.

### F.16.2. hstore Operators and Functions

The operators provided by the hstore module are shown in Table F-8, the functions in Table F-9.

#### Table F-8. hstore Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>hstore -&gt; text</td>
<td>get value for key (NULL if not present)</td>
<td>‘a=&gt;x, b=&gt;y’::hstore -&gt; ‘a’</td>
<td>x</td>
</tr>
<tr>
<td>hstore -&gt; text[]</td>
<td>get values for keys (NULL if not present)</td>
<td>‘a=&gt;x, b=&gt;y, c=&gt;z’::hstore -&gt; ARRAY['c','a']</td>
<td>{&quot;z&quot;,&quot;x&quot;}</td>
</tr>
<tr>
<td>hstore</td>
<td></td>
<td>hstore</td>
<td>concatenate hstores</td>
</tr>
<tr>
<td>hstore ? text</td>
<td>does hstore contain key?</td>
<td>‘a=&gt;1’::hstore ? ‘a’</td>
<td>t</td>
</tr>
<tr>
<td>hstore ?&amp; text[]</td>
<td>does hstore contain all specified keys?</td>
<td>‘a=&gt;1,b=&gt;2’::hstore ?&amp; ARRAY[‘a’,’b’]</td>
<td></td>
</tr>
<tr>
<td>hstore ?</td>
<td>text[]</td>
<td>does hstore contain any of the specified keys?</td>
<td>‘a=&gt;1,b=&gt;2’::hstore ? ARRAY[‘b’,’c’]</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>hstore @&gt; hstore</td>
<td>does left operand contain right?</td>
<td>'a' =&gt; b, b =&gt; 1, c =&gt; NULL'::hstore @&gt; 'b' =&gt; 1'</td>
<td>t</td>
</tr>
<tr>
<td>hstore &lt;@ hstore</td>
<td>is left operand contained in right?</td>
<td>'a' =&gt; c'::hstore &lt;@ 'a' =&gt; b, b =&gt; 1, c =&gt; NULL'</td>
<td>f</td>
</tr>
<tr>
<td>hstore - text</td>
<td>delete key from left operand</td>
<td>'a' =&gt; 1, b =&gt; 2, c =&gt; 3'::hstore - 'b' :: text</td>
<td>&quot;a&quot; =&gt; &quot;1&quot;, &quot;c&quot; =&gt; &quot;3&quot;</td>
</tr>
<tr>
<td>hstore - text[]</td>
<td>delete keys from left operand</td>
<td>'a' =&gt; 1, b =&gt; 2, c =&gt; 3'::hstore - ARRAY['a', 'b']</td>
<td>&quot;c&quot; =&gt; &quot;3&quot;</td>
</tr>
<tr>
<td>hstore - hstore</td>
<td>delete matching pairs from left operand</td>
<td>'a' =&gt; 1, b =&gt; 2, c =&gt; 3'::hstore - 'a' =&gt; 4, b =&gt; 2' :: hstore</td>
<td>&quot;a&quot; =&gt; &quot;1&quot;, &quot;c&quot; =&gt; &quot;3&quot;</td>
</tr>
<tr>
<td>record #= hstore</td>
<td>replace fields in record with matching</td>
<td>see Examples section</td>
<td></td>
</tr>
<tr>
<td></td>
<td>values from hstore</td>
<td></td>
<td></td>
</tr>
<tr>
<td>% % hstore</td>
<td>convert hstore to array of alternating</td>
<td>% % 'a' =&gt; foo, b =&gt; bar' :: hstore</td>
<td>{a, foo, b, bar}</td>
</tr>
<tr>
<td></td>
<td>keys and values</td>
<td></td>
<td></td>
</tr>
<tr>
<td>% # hstore</td>
<td>convert hstore to two-dimensional key/value array</td>
<td>% % 'a' =&gt; foo, b =&gt; bar' :: hstore</td>
<td>{{a, foo}, {b, bar}}</td>
</tr>
</tbody>
</table>

**Note:** Prior to PostgreSQL 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

### Table F-9. hstore Functions

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

**Note:** The function `hstore_to_json` is used when an hstore value is cast to json. Likewise, `hstore_to_jsonb` is used when an hstore value is cast to jsonb.
Appendix F. Additional Supplied Modules

Note: The function populate_record is actually declared with anyelement, not record, as its first argument, but it will reject non-record types with a run-time error.

F.16.3. Indexes

hstore has GiST and GIN index support for the $>,$ $\?, $?$,$ and $?$ operators. For example:

CREATE INDEX hidx ON testhstore USING GIST (h);
CREATE INDEX hidx ON testhstore USING GIN (h);

hstore also supports btree or hash indexes for the $=$ operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for $=$ comparisons as follows:

CREATE INDEX hidx ON testhstore USING BTREE (h);
CREATE INDEX hidx ON testhstore USING HASH (h);

F.16.4. Examples

Add a key, or update an existing key with a new value:

UPDATE tab SET h = h || hstore('c', '3');

Delete a key:

UPDATE tab SET h = delete(h, 'k1');

Convert a record to an hstore:

CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
SELECT hstore(t) FROM test AS t;

hstore

"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)

Convert an hstore to a predefined record type:

CREATE TABLE test (col1 integer, col2 text, col3 text);
SELECT * FROM populate_record(null::test, "col1"=>"456", "col2"=>"zzz");

col1 | col2 | col3
Modify an existing record using the values from an hstore:

```sql
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
SELECT (r).* FROM (SELECT t #= "col3"="baz" AS r FROM test t) s;
```

```
  col1 | col2 | col3
  ------|------|------
    123 | foo  | baz
(1 row)
```

### F.16.5. Statistics

The hstore type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

**Simple example:**

```sql
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

**Using a table:**

```sql
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

**Online statistics:**

```sql
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

```
  key | count
  ------+-------
    line    |    883
    query   |    207
    pos     |    203
    node    |    202
    space   |    197
     status |    195
    public  |    194
     title  |    190
     org    |    189
```

...............
F.16.6. Compatibility

As of PostgreSQL 9.0, hstore uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an UPDATE statement as follows:

UPDATE tablename SET hstorecol = hstorecol || "";

Another way to do it is:

ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || "";

The ALTER TABLE method requires an exclusive lock on the table, but does not result in bloating the table with old row versions.

F.16.7. Transforms

Additional extensions are available that implement transforms for the hstore type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called hstore_plperl and hstore_plperlu, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, hstore values are mapped to Perl hashes. The extensions for PL/Python are called hstore_plpythonu, hstore_plpython2u, and hstore_plpython3u (see Section 44.1 for the PL/Python naming convention). If you use them, hstore values are mapped to Python dictionaries.

F.16.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia
Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@taol1.riddles.org.uk>, United Kingdom

F.17. intagg

The intagg module provides an integer aggregator and an enumerator. intagg is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.
F.17.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.17.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.*, from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
  SELECT left, int_array_aggregate(right) AS right
  FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that’s why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
  )
```
F.18. intarray

The intarray module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any NULL elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

F.18.1. intarray Functions and Operators

The functions provided by the intarray module are shown in Table F-10, the operators in Table F-11.

Table F-10. intarray Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>int[] &amp; int[]</td>
<td>int[]</td>
<td>intersection of arrays</td>
</tr>
<tr>
<td>int[] @@ query_int</td>
<td>boolean</td>
<td>true if array satisfies query (see below)</td>
</tr>
<tr>
<td>query_int ~~~ int[]</td>
<td>boolean</td>
<td>true if array satisfies query (commutator of @@)</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators @> and <@ were respectively called @ and ~. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators &&, @> and <@ are equivalent to PostgreSQL’s built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The @@ and ~~~ operators test whether an array satisfies a query, which is expressed as a value of a specialized data type query_int. A query consists of integer values that are checked against the elements of the array, possibly combined using the operators & (AND), | (OR), and ! (NOT). Parentheses can be used as needed. For example, the query 1& (2|3) matches arrays that contain 1 and also contain either 2 or 3.
F.18.2. Index Support

`intarray` provides index support for the `&&`, `@>`, `<@`, and `@@` operators, as well as regular array equality.

Two GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.18.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__int_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2':query_int;
```

F.18.4. Benchmark

The source directory `contrib/intarray/bench` contains a benchmark test suite, which can be run against an installed PostgreSQL server. (It also requires `DBD::Pg` to be installed.) To run:

```
    cd .../contrib/intarray/bench
    createdb TEST
    psql -c "CREATE EXTENSION intarray" TEST
    ./create_test.pl | psql TEST
    ./bench.pl
```

The `bench.pl` script has numerous options, which are displayed when it is run without any arguments.

F.18.5. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See http://www.sai.msu.su/~megera/postgres/gist/ for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.
Appendix F. Additional Supplied Modules

F.19. isn

The isn module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

F.19.1. Data Types

Table F-12 shows the data types provided by the isn module.

Table F-12. isn Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAN13</td>
<td>European Article Numbers, always displayed in the EAN13 display format</td>
</tr>
<tr>
<td>ISBN13</td>
<td>International Standard Book Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISMN13</td>
<td>International Standard Music Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISSN13</td>
<td>International Standard Serial Numbers to be displayed in the new EAN13 display format</td>
</tr>
<tr>
<td>ISBN</td>
<td>International Standard Book Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISMN</td>
<td>International Standard Music Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>ISSN</td>
<td>International Standard Serial Numbers to be displayed in the old short display format</td>
</tr>
<tr>
<td>UPC</td>
<td>Universal Product Codes</td>
</tr>
</tbody>
</table>

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren’t always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.
Appendix F: Additional Supplied Modules

The ISBN, ISMN, and ISSN types will display the short version of the number (ISxN 10) whenever it’s possible, and will show ISxN 13 format for numbers that do not fit in the short version. The EAN13, ISBN13, ISMN13 and ISSN13 types will always display the long version of the ISxN (EAN13).

F.19.2. Casts

The isn module provides the following pairs of type casts:

- ISBN13 <=> EAN13
- ISMN13 <=> EAN13
- ISSN13 <=> EAN13
- ISBN <=> EAN13
- ISMN <=> EAN13
- ISSN <=> EAN13
- UPC <=> EAN13
- ISMN <=> ISMN13
- ISSN <=> ISSN13

When casting from EAN13 to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.19.3. Functions and Operators

The isn module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in Table F-13. In this table, isn means any one of the module’s data types.

Table F-13. isn Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isn_weak(boolean)</td>
<td>boolean</td>
<td>Sets the weak input mode (returns new setting)</td>
</tr>
<tr>
<td>isn_weak()</td>
<td>boolean</td>
<td>Gets the current status of the weak mode</td>
</tr>
<tr>
<td>make_valid(isn)</td>
<td>isn</td>
<td>Validates an invalid number (clears the invalid flag)</td>
</tr>
<tr>
<td>is_valid(isn)</td>
<td>boolean</td>
<td>Checks for the presence of the invalid flag</td>
</tr>
</tbody>
</table>

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong,
perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to
clean the mess up, but you still want to be able to have all the numbers in your database and maybe
use an external tool to locate the invalid numbers in the database so you can verify the information
and validate it more easily; so for example you’d want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the
corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example
0-11-000322-5!. This invalid marker can be checked with the is_valid function and cleared with the
make_valid function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending
the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct
check digit will be inserted automatically.

F.19.4. Examples

--Using the types directly:
SELECT isbn(‘978-0-393-04002-9’);
SELECT isbn13(‘09016905456’);
SELECT issn(‘1436-4522’);

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13(‘0220356483481’));
-- but these will:
SELECT upc(ean13(‘0220356483481’));
SELECT ean13(upc(‘220356483481’));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES(‘9780393040029’);

--Automatically calculate check digits (observe the ‘?’):
INSERT INTO test VALUES(‘220500896?’);
INSERT INTO test VALUES(‘978055215372?’);

SELECT issn(‘3251231?’);
SELECT ismn(‘979047213542?’);

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES(‘978-0-11-000533-4’);
INSERT INTO test VALUES(‘9780141219307’);
INSERT INTO test VALUES(‘2-205-00876-X’);
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = ’2-205-00876-X’;

SELECT isbn13(id) FROM test;
F.19.5. Bibliography

The information to implement this module was collected from several sites, including:

- http://www.isbn-international.org/
- http://www.issn.org/
- http://www.ismn-international.org/
- http://www.wikipedia.org/

The prefixes used for hyphenation were also compiled from:

- http://www.gs1.org/productssolutions/idkeys/support/prefix_list.html
- https://www.isbn-international.org/content/isbn-users-manual
- http://www.ismn-international.org/ranges.html

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.19.6. Author

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman's isbn_issn code.

F.20. lo

The lo module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type lo and a trigger lo_manage.

F.20.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large OBjects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As PostgreSQL stands, this doesn’t occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn’t delete the large object just because you change or remove one such entry.

Now this is fine for PostgreSQL-specific applications, but standard code using JDBC or ODBC won’t delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The lo module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a lo_unlink whenever you delete or modify a value referencing a
large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type lo, which is really just a domain of the oid type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don’t have to use the lo type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don’t use lo for BLOB columns.

**F.20.2. How to Use It**

Here’s a simple example of usage:

```sql
CREATE TABLE image (title TEXT, raster lo);
CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
    FOR EACH ROW EXECUTE PROCEDURE lo_manage(raster);
```

For each column that will contain unique references to large objects, create a BEFORE UPDATE OR DELETE trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using BEFORE UPDATE OF column_name. If you need multiple lo columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

**F.20.3. Limitations**

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the DROP TABLE with DELETE FROM table.
  TRUNCATE has the same hazard.

  If you already have, or suspect you have, orphaned large objects, see the vacuumlo module to help you clean them up. It’s a good idea to run vacuumlo occasionally as a back-stop to the lo_manage trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

**F.20.4. Author**

Peter Mount <peter@retep.org.uk>

**F.21. ltree**

This module implements a data type ltree for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.
F.21.1. Definitions

A label is a sequence of alphanumeric characters and underscores (for example, in C locale the characters A-Za-z0-9_ are allowed). Labels must be less than 256 bytes long.

Examples: 42, Personal_Services

A label path is a sequence of zero or more labels separated by dots, for example L1.L2.L3, representing a path from the root of a hierarchical tree to a particular node. The length of a label path must be less than 65kB, but keeping it under 2kB is preferable.

Example: Top.Countries.Europe.Russia

The ltree module provides several data types:

- ltree stores a label path.
- lquery represents a regular-expression-like pattern for matching ltree values. A simple word matches that label within a path. A star symbol (*) matches zero or more labels. For example:

```
foo
*.foo.*
+.foo
```

Star symbols can also be quantified to restrict how many labels they can match:

```
*{n} Match exactly n labels
*{n,} Match at least n labels
*{n,m} Match at least n but not more than m labels
*{0,m} Match at most m labels -- same as *{0,m}
```

There are several modifiers that can be put at the end of a non-star label in lquery to make it match more than just the exact match:

```
@
*%  
```

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example foo_bar% matches foo_bar_baz but not foo_bar baz. If combined with *, prefix matching applies to each word separately, for example foo_bar%* matches foo1_bar2_baz but not foo1_br2_baz.

Also, you can write several possibly-modified labels separated with | (OR) to match any of those labels, and you can put ! (NOT) at the start to match any label that doesn’t match any of the alternatives.

Here’s an annotated example of lquery:

```
Top.*{0,2}.sport@!.football|tennis.Russ*|Spain
```

This query will match any label path that:

- a. begins with the label Top
- b. and next has zero to two labels before
- c. a label beginning with the case-insensitive prefix sport
- d. then a label not matching football nor tennis
- e. and then ends with a label beginning with Russ or exactly matching Spain.
Appendix F. Additional Supplied Modules

- `ltxtquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxtquery` value contains words, possibly with the modifiers @, *, % at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with & (AND), | (OR), ! (NOT), and parentheses. The key difference from `lquery` is that `ltxtquery` matches words without regard to their position in the label path.

Here’s an example `ltxtquery`:

Europe & Russia* & !Transportation

This will match paths that contain the label Europe and any label beginning with Russia (case-insensitive), but not paths containing the label Transportation. The location of these words within the path is not important. Also, when % is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxtquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.21.2. Operators and Functions

Type `ltree` has the usual comparison operators =, <>, <, >, <=, >=. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in Table F-14 are available.

### Table F-14. `ltree` Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ltree @ ltree</code></td>
<td>boolean</td>

<td>does array contain an ancestor of <code>ltree</code>?</td>
</tr>
<tr>
<td><code>ltree &lt;@ ltree[]</code></td>
<td>boolean</td>
<td>does array contain an ancestor of <code>ltree</code>?</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ltree[] &lt;@ ltree</td>
<td>boolean</td>
<td>does array contain a descendant of ltree?</td>
</tr>
<tr>
<td>ltree @&gt; ltree[]</td>
<td>boolean</td>
<td>does array contain a descendant of ltree?</td>
</tr>
<tr>
<td>ltree[] ~ lquery</td>
<td>boolean</td>
<td>does array contain any path matching lquery?</td>
</tr>
<tr>
<td>lquery ~ ltree[]</td>
<td>boolean</td>
<td>does array contain any path matching lquery?</td>
</tr>
<tr>
<td>ltree[] ? lquery[]</td>
<td>boolean</td>
<td>does ltree array contain any path matching any lquery?</td>
</tr>
<tr>
<td>lquery[] ? ltree[]</td>
<td>boolean</td>
<td>does ltree array contain any path matching any lquery?</td>
</tr>
<tr>
<td>ltree[] @ ltxtquery</td>
<td>boolean</td>
<td>does array contain any path matching ltxtquery?</td>
</tr>
<tr>
<td>ltxtquery @ ltree[]</td>
<td>boolean</td>
<td>does array contain any path matching ltxtquery?</td>
</tr>
<tr>
<td>ltree[] ?@&gt; ltree</td>
<td>ltree</td>
<td>first array entry that is an ancestor of ltree; NULL if none</td>
</tr>
<tr>
<td>ltree[] ?&lt;@ ltree</td>
<td>ltree</td>
<td>first array entry that is a descendant of ltree; NULL if none</td>
</tr>
<tr>
<td>ltree[] ?~ lquery</td>
<td>ltree</td>
<td>first array entry that matches lquery; NULL if none</td>
</tr>
<tr>
<td>ltree[] ?@ ltxtquery</td>
<td>ltree</td>
<td>first array entry that matches ltxtquery; NULL if none</td>
</tr>
</tbody>
</table>

The operators <@, @>, @ and ~ have analogues ^<@, ^@>, ^@, ^~, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in Table F-15.

Table F-15. ltree Functions

<table>
<thead>
<tr>
<th>Function (ltree, int start, int end)</th>
<th>Return Type</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>

<td>text</td>
<td>cast ltree to text</td>
<td></td>
<td></td>
</tr>
<tr>
<td>lca(ltree, ltree, ...)</td>
<td>ltree</td>
<td>longest common ancestor of paths (up to 8 arguments supported)</td>
<td>lca('1.2.3', '1.2.4.5.6')</td>
<td></td>
</tr>
<tr>
<td>lca(ltree[])</td>
<td>ltree</td>
<td>longest common ancestor of paths in array</td>
<td>lca(array['1.2.3.4', '1.2.3.4.5.6'])</td>
<td></td>
</tr>
</tbody>
</table>
F.21.3. Indexes

ltree supports several types of indexes that can speed up the indicated operators:

- **B-tree index over ltree:<,<=,=,>,>=**
- **GiST index over ltree:<,<=,=,>,@,>,<@,<>**

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

- **GiST index over ltree[]):ltree[]:<@ ltree] ltree[]>@ ltree[],@,~,**

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Note: This index type is lossy.

F.21.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```sql
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```
Top
/|\   
Science Hobbies Collections
/ | \   
Astronomy Amateurs_Astronomy Pictures
/ \   
Astrophysics Cosmology Astronomy
/   | \   
Galaxies Stars Astronauts
```

We can do inheritance:

```
ltree=› SELECT path FROM test WHERE path <@ 'Top.Science';
```

```
path
```

2415
Appendix F: Additional Supplied Modules

Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(4 rows)

Here are some examples of path matching:

ltree=>
SELECT path FROM test WHERE path ~ '*.Astronomy.*';
path
-----------------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Collections.Pictures.Astronomy
(7 rows)

ltree=>
SELECT path FROM test WHERE path ~ '*.!pictures@.*.Astronomy.*';
path
------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(3 rows)

Here are some examples of full text search:

ltree=>
SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
path
------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Hobbies.Amateurs_Astronomy
(4 rows)

ltree=>
SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
path
------------------------------------
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
(3 rows)

Path construction using functions:

ltree=>
SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@ 'Top.Science.Space.Astronomy';
?column?
------------------------------------------
Top.Science.Space.Astronomy

2416
We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```sql
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
    AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
    LANGUAGE SQL IMMUTABLE;
```

```sql
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <<@ 'Top.Science.Astronomy';
```

```
Top.Science.Space.Astronomy
```

**F.21.5. Transforms**

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see Section 44.1 for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

**F.21.6. Authors**

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See [http://www.sai.msu.su/~megera/postgres/gist/](http://www.sai.msu.su/~megera/postgres/gist/) for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

**F.22. pageinspect**

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

**F.22.1. Functions**

```sql
get_raw_page(relname text, fork text, blkno int) returns bytea
```

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. `fork` should be
Appendix F. Additional Supplied Modules

'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

get_raw_page( relname text, blkno int ) returns bytea

A shorthand version of get_raw_page, for reading from the main fork. Equivalent to get_raw_page( relname, 'main', blkno )

page_header( page bytea ) returns record

page_header shows fields that are common to all PostgreSQL heap and index pages.

A page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM page_header( get_raw_page( 'pg_class', 0 ) );

lsn | checksum | flags | lower | upper | special | pagesize | version | prune_xid
-----------+----------+--------+-------+-------+---------+----------+---------+-----------
0/24A1B50 | 1 | 1 | 232 | 368 | 8192 | 8192 | 4 | 0

The returned columns correspond to the fields in the PageHeaderData struct. See src/include/storage/bufpage.h for details.

heap_page_items( page bytea ) returns setof record

heap_page_items shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM heap_page_items( get_raw_page( 'pg_class', 0 ) );

See src/include/storage/itemid.h and src/include/access/htup_details.h for explanations of the fields returned.

tuple_data_split( rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]

tuple_data_split splits tuple data into attributes in the same way as backend internals.

test=# SELECT tuple_data_split( 'pg_class':regclass, t_data, t_infomask, t_infomask2, t_bits ) FROM heap_page_items( get_raw_page( 'pg_class', 0 ) );

This function should be called with the same arguments as the return attributes of heap_page_items.

If do_detoast is true, attribute that will be detoasted as needed. Default value is false.

heap_page_item_attrs( page bytea, rel_oid regclass [, do_detoast bool]) returns setof record

heap_page_item_attrs is equivalent to heap_page_items except that it returns tuple raw data as an array of attributes that can optionally be detoasted by do_detoast which is false by default.

A heap page image obtained with get_raw_page should be passed as argument. For example:

test=# SELECT * FROM heap_page_item_attrs( get_raw_page( 'pg_class', 0 ) , 'pg_class':regclass, do_detoast );

bt_metap( relname text ) returns record

bt_metap returns information about a B-tree index’s metapage. For example:

test=# SELECT * FROM bt_metap( 'pg_cast_oid_index' );

-| [ RECORD 1 ]-----
magic | 340322
version | 2
root | 1
level | 0
fastroot | 1

2418
Appendix F. Additional Supplied Modules

fastlevel | 0

bt_page_stats(relname text, blkno int) returns record

bt_page_stats returns summary information about single pages of B-tree indexes. For example:

test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
<table>
<thead>
<tr>
<th>blkno</th>
<th>type</th>
<th>live_items</th>
<th>dead_items</th>
<th>avg_item_size</th>
<th>page_size</th>
<th>free_size</th>
<th>btpo_prev</th>
<th>btpo_next</th>
<th>btpo</th>
<th>btpo_flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>l</td>
<td>256</td>
<td>0</td>
<td>12</td>
<td>8192</td>
<td>4056</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

bt_page_items(relname text, blkno int) returns setof record

bt_page_items returns detailed information about all of the items on a B-tree index page. For example:

test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
<table>
<thead>
<tr>
<th>itemoffset</th>
<th>ctid</th>
<th>itemlen</th>
<th>nulls</th>
<th>vars</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(0,1)</td>
<td>12</td>
<td>f</td>
<td>f</td>
<td>23 27 00 00</td>
</tr>
<tr>
<td>2</td>
<td>(0,2)</td>
<td>12</td>
<td>f</td>
<td>f</td>
<td>24 27 00 00</td>
</tr>
<tr>
<td>3</td>
<td>(0,3)</td>
<td>12</td>
<td>f</td>

<td>(0,7)</td>
<td>12</td>
<td>f</td>
<td>f</td>
<td>29 27 00 00</td>
</tr>
<tr>
<td>8</td>
<td>(0,8)</td>
<td>12</td>
<td>f</td>
<td>f</td>
<td>2a 27 00 00</td>
</tr>
</tbody>
</table>

In a B-tree leaf page, ctid points to a heap tuple. In an internal page, the block number part of ctid points to another page in the index itself, while the offset part (the second number) is ignored and is usually 1.

Note that the first item on any non-rightmost page (any page with a non-zero value in the btpo_next field) is the page’s “high key”, meaning its data serves as an upper bound on all items appearing on the page, while its ctid field is meaningless. Also, on non-leaf pages, the first real data item (the first item that is not a high key) is a “minus infinity” item, with no actual value in its data field. Such an item does have a valid downlink in its ctid field, however.

brin_page_type(page bytea) returns text

brin_page_type returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
<table>
<thead>
<tr>
<th>brin_page_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>meta</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

brin_metapage_info(page bytea) returns record

*brin_metapage_info* returns assorted information about a BRIN index metapage. For example:

```sql
test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
  magic | version | pagesperrange | lastrevmappage
---------+---------+-------------+----------------
  0xA8109CFA | 1 | 4 | 2
```

brin_revmap_data(page bytea) returns setof tid

*brin_revmap_data* returns the list of tuple identifiers in a BRIN index range map page. For example:

```sql
test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) limit 5;
  pages
----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)
```

brin_page_items(page bytea, index oid) returns setof record

*brin_page_items* returns the data stored in the BRIN data page. For example:

```sql
test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5), 'brinidx')
ORDER BY blknum, attnum LIMIT 6;
    itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
--------------+--------+--------+----------+----------+-------------+--------------
    137 | 0 | 1 | t | f | f | {1 .. 88}
    137 | 0 | 2 | f | f | f | {89 .. 176}
    138 | 4 | 1 | t | f | f | {177 .. 264}
    138 | 4 | 2 | f | f | f | {177 .. 264}
    139 | 8 | 1 | t | f | f | {177 .. 264}
    139 | 8 | 2 | f | f | f | {177 .. 264}
```

The returned columns correspond to the fields in the *BrinMemTuple* and *BrinValues* structs. See `src/include/access/brin_tuple.h` for details.

gin_metapage_info(page bytea) returns record

*gin_metapage_info* returns information about a GIN index metapage. For example:

```sql
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
- [ RECORD 1 ] -------------------------
  pending_head | 4294967295
  pending_tail | 4294967295
  tail_free_size | 0
  n_pending_pages | 0
  n_pending_tuples | 0
  n_total_pages | 7
  n_entry_pages | 6
  n_data_pages | 0
  n_entries | 693
  version | 2
```

2420
Appendix F. Additional Supplied Modules

gin_page_opaque_info(page bytea) returns record

    gin_page_opaque_info returns information about a GIN index opaque area, like the page type. For example:

    test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));

    rightlink | maxoff | flags
    -----------+--------+------------------------
    5 | 0 | {data,leaf,compressed}
    (1 row)

    gin_leafpage_items(page bytea) returns setof record

    gin_leafpage_items returns information about the data stored in a GIN leaf page. For example:

    test=# SELECT first_tid, nbytes, tids[0:5] as some_tids
        FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));

    first_tid | nbytes | some_tids
    -----------+--------+----------------------------------------------------------
    (8,41) | 244 | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
    (10,45) | 248 | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
    (12,52) | 248 | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
    (14,59) | 320 | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}

    (7 rows)

    fsm_page_contents(page bytea) returns text

    fsm_page_contents shows the internal node structure of a FSM page. The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

    See src/backend/storage/freespace/README for more information on the structure of an FSM page.

F.23. passwordcheck

The passwordcheck module checks users’ passwords whenever they are set with CREATE ROLE or ALTER ROLE. If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add ‘$libdir/passwordcheck’ to shared_preload_libraries in postgresql.conf, then restart the server.

You can adapt this module to your needs by changing the source code. For example, you can use CrackLib to check passwords — this only requires uncommenting two lines in the Makefile and rebuilding the module. (We cannot include CrackLib by default for license reasons.) Without CrackLib, the module enforces a few simple rules for password strength, which you can modify or extend as you see fit.

Caution
To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, PostgreSQL allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see Chapter 20) than to rely on passwords within the database.

Alternatively, you could modify `passwordcheck` to reject pre-encrypted passwords, but forcing users to set their passwords in clear text carries its own security risks.

F.24. pg_buffercache

The `pg_buffercache` module provides a means for examining what’s happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default public access is revoked from both of these, just in case there are security issues lurking.

F.24.1. The `pg_buffercache` View

The definitions of the columns exposed by the view are shown in Table F-16.

Table F-16. `pg_buffercache` Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>References</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bufferid</td>
<td>integer</td>
<td></td>
<td>ID, in the range <code>1..shared_buffers</code></td>
</tr>

</tr>
</thead>
<tbody>
<tr>
<td>usagecount</td>
<td>smallint</td>
<td></td>
<td>Clock-sweep access count</td>
</tr>
<tr>
<td>pinning_backends</td>
<td>integer</td>
<td></td>
<td>Number of backends pinning this buffer</td>
</tr>
</tbody>
</table>

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except bufferid. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it’s a good idea to restrict the join to rows having `reldatabase` equal to the current database’s OID or zero.

When the `pg_buffercache` view is accessed, internal buffer manager locks are taken for long enough to copy all the buffer state data that the view will display. This ensures that the view produces a consistent set of results, while not blocking normal buffer activity longer than necessary. Nonetheless there could be some impact on database performance if this view is read often.

#### F.24.2. Sample Output

```sql
regression=# SELECT c.relname, count(*) AS buffers
  FROM pg_buffercache b INNER JOIN pg_class c
  ON b.relfilenode = pg_relation_filenode(c.oid) AND
  b.reldatabase IN (0, (SELECT oid FROM pg_database
                        WHERE datname = current_database()))
  GROUP BY c.relname
  ORDER BY 2 DESC
  LIMIT 10;
```

```
relname | buffers
--------+---------
tenk2   | 345
tenk1   | 141
pg_proc | 46
pg_class | 45
pg_attribute | 43

Design suggestions: Neil Conway &lt;neilc@samurai.com&gt;

Debugging advice: Tom Lane &lt;tgl@sss.pgh.pa.us&gt;
Appendix F. Additional Supplied Modules

F.25. pgcrypto

The pgcrypto module provides cryptographic functions for PostgreSQL.

F.25.1. General Hashing Functions

F.25.1.1. digest()

digest(data text, type text) returns bytea  
digest(data bytea, type text) returns bytea

Computes a binary hash of the given data. type is the algorithm to use. Standard algorithms are md5, sha1, sha224, sha256, sha384 and sha512. If pgcrypto was built with OpenSSL, more algorithms are available, as detailed in Table F-20.

If you want the digest as a hexadecimal string, use encode() on the result. For example:

CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;

F.25.1.2. hmac()

hmac(data text, key text, type text) returns bytea  
hmac(data bytea, key bytea, type text) returns bytea

Calculates hashed MAC for data with key. type is the same as in digest().

This is similar to digest() but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.25.2. Password Hashing Functions

The functions crypt() and gen_salt() are specifically designed for hashing passwords. crypt() does the hashing and gen_salt() prepares algorithm parameters for it.

The algorithms in crypt() differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the salt, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

Table F-17 lists the algorithms supported by the crypt() function.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Max Password Length</th>
<th>Adaptive?</th>
<th>Salt Bits</th>
<th>Output Length</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bf</td>
<td>72</td>
<td>yes</td>
<td>128</td>
<td>60</td>
<td>Blowfish-based, variant 2a</td>
</tr>
<tr>
<td>md5</td>
<td>unlimited</td>
<td>no</td>
<td>48</td>
<td>34</td>
<td>MD5-based crypt</td>
</tr>
<tr>
<td>xdes</td>
<td>8</td>
<td>yes</td>
<td>24</td>
<td>20</td>
<td>Extended DES</td>
</tr>
<tr>
<td>des</td>
<td>8</td>
<td>no</td>
<td>12</td>
<td>13</td>
<td>Original UNIX crypt</td>
</tr>
</tbody>
</table>

**F.25.2.1. crypt()**

crypt(password text, salt text) returns text

Calculates a crypt(3)-style hash of password. When storing a new password, you need to use gen_salt() to generate a new salt value. To check a password, pass the stored hash value as salt, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns true if the entered password is correct.

**F.25.2.2. gen_salt()**

gen_salt(type text [, iter_count integer ]) returns text

Generates a new random salt string for use in crypt(). The salt string also tells crypt() which algorithm to use.

The type parameter specifies the hashing algorithm. The accepted types are: des, xdes, md5 and bf.

The iter_count parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the iter_count parameter is omitted, the default iteration count is used. Allowed values for iter_count depend on the algorithm and are shown in Table F-18.
Appendix F. Additional Supplied Modules

Table F-18. Iteration Counts for crypt()

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>xdes</td>
<td>725</td>
<td>1</td>
<td>16777215</td>
</tr>
<tr>
<td>bf</td>
<td>6</td>
<td>4</td>
<td>31</td>
</tr>
</tbody>
</table>

For xdes there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES crypt was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

Table F-19 gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the crypt-bf entries, the number after a slash is the iter_count parameter of gen_salt.

Table F-19. Hash Algorithm Speeds

<table>
<thead>
<tr>

<td>1</td>
</tr>
</tbody>
</table>

Notes:

- The machine used is an Intel Mobile Core i3.
- crypt-des and crypt-md5 algorithm numbers are taken from John the Ripper v1.6.38 -test output.
- md5 hash numbers are from mdcrack 1.2.
- sha1 numbers are from lcrack-20031130-beta.
- crypt-bf numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: john -test shows 13506 loops/sec for crypt-bf/5. (The very small difference in results is in accordance with the fact that the crypt-bf implementation in pgcrypto is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.
F.25.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or packets:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to crypt() algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.25.3.1. pgp_sym_encrypt()

pgp_sym_encrypt(data text, psw text [, options text ]) returns bytea
pgp_sym_encrypt_bytea(data bytea, psw text [, options text ]) returns bytea

Encrypt data with a symmetric PGP key psw. The options parameter can contain option settings, as described below.

F.25.3.2. pgp_sym_decrypt()

pgp_sym_decrypt(msg bytea, psw text [, options text ]) returns text
pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ]) returns bytea

Decrypt a symmetric-key-encrypted PGP message.

Decrypting bytea data with pgp_sym_decrypt is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with pgp_sym_decrypt_bytea is fine.
Appendix F. Additional Supplied Modules

The `options` parameter can contain option settings, as described below.

### F.25.3.3. `pgp_pub_encrypt()`

pgp_pub_encrypt(data text, key bytea [, options text ]) returns bytea
pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ]) returns bytea

Encrypt data with a public PGP key. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

### F.25.3.4. `pgp_pub_decrypt()`

pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]]) returns text
pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]]) returns bytea

Decrypt a public-key-encrypted message. `key` must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in `psw`.

If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

### F.25.3.5. `pgp_key_id()`

pgp_key_id(bytea) returns text

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- **SYMKEY**
  
The message is encrypted with a symmetric key.

- **ANYKEY**
  
The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

### F.25.3.6. `armor()`, `dearmor()`

armor(data bytea [, , keys text[], values text[] ]) returns text
dearmor(data text) returns bytea

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.
If the keys and values arrays are specified, an armor header is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.25.3.7. pgp_armor_headers

`pgp_armor_headers(data text, key out text, value out text) returns setof record`

`pgp_armor_headers()` extracts the armor headers from `data`. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.25.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option’s value should be given after an equal sign; separate options from each other with commas. For example:

`pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')`

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.25.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)
Default: aes128
Applies to: `pgp_sym_encrypt, pgp_pub_encrypt`

F.25.3.8.2. compress-algo

Which compression algorithm to use. Only available if PostgreSQL was built with zlib.

Values:
0 - no compression
1 - ZIP compression
2 - ZLIB compression (= ZIP plus meta-data and block CRCs)
Default: 0
Applies to: `pgp_sym_encrypt, pgp_pub_encrypt`

F.25.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9
Default: 6
Appendix F. Additional Supplied Modules

Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.25.3.8.4. convert-crlf
Whether to convert \n into \r\n when encrypting and \r\n to \n when decrypting. RFC 4880 specifies that text data should be stored using \r\n line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt, pgp_sym_decrypt, pgp_pub_decrypt

F.25.3.8.5. disable-mdc
Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.25.3.8.6. sess-key
Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt

F.25.3.8.7. s2k-mode
Which S2K algorithm to use.

Values:
  0 - Without salt. Dangerous!
  1 - With salt but with fixed iteration count.
  3 - Variable iteration count.
Default: 3
Applies to: pgp_sym_encrypt

F.25.3.8.8. s2k-count
The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952
Applies to: pgp_sym_encrypt, only with s2k-mode=3
Appendix F. Additional Supplied Modules

F.25.3.8.9. s2k-digest-algo
Which digest algorithm to use in S2K calculation.
Values: md5, sha1
Default: sha1
Applies to: pgp_sym_encrypt

F.25.3.8.10. s2k-cipher-algo
Which cipher to use for encrypting separate session key.
Values: bf, aes, aes128, aes192, aes256
Default: use cipher-algo
Applies to: pgp_sym_encrypt

F.25.3.8.11. unicode-mode
Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.
Values: 0, 1
Default: 0
Applies to: pgp_sym_encrypt, pgp_pub_encrypt

F.25.3.9. Generating PGP Keys with GnuPG

To generate a new key:

gpg --gen-key

The preferred key type is “DSA and Elgamal”.
For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with gpg --edit-key.
To list keys:

gpg --list-secret-keys

To export a public key in ASCII-armor format:

gpg -a --export KEYID > public.key

To export a secret key in ASCII-armor format:

gpg -a --export-secret-keys KEYID > secret.key
You need to use \texttt{dearmor()} on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop \texttt{-a} from the command.

For more details see \texttt{man gpg}, The GNU Privacy Handbook\textsuperscript{4} and other documentation on http://www.gnupg.org.

\textbf{F.25.3.10. Limitations of PGP Code}

\begin{itemize}
\item No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
\item No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
\item No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with \texttt{pgcrypto}, but create new ones, as the usage scenario is rather different.
\end{itemize}

\textbf{F.25.4. Raw Encryption Functions}

These functions only run a cipher over data; they don’t have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don’t provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don’t handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

\begin{verbatim}
encrypt(data bytea, key bytea, type text) returns bytea
decrypt(data bytea, key bytea, type text) returns bytea
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
\end{verbatim}

Encrypt/decrypt data using the cipher method specified by \texttt{type}. The syntax of the \texttt{type} string is:

\begin{verbatim}
algorithm [ - mode ] [ /pad: padding ]
\end{verbatim}

where \texttt{algorithm} is one of:

\begin{itemize}
\item \textbf{bf} — Blowfish
\item \textbf{aes} — AES (Rijndael-128, -192 or -256)
\end{itemize}

and \texttt{mode} is one of:

\textsuperscript{4} http://www.gnupg.org/gph/en/manual.html
Appendix F. Additional Supplied Modules

- **cbc** — next block depends on previous (default)
- **ecb** — each block is encrypted separately (for testing only)

and *padding* is one of:

- **pkcs** — data may be any length (default)
- **none** — data must be multiple of cipher block size

So, for example, these are equivalent:

```plaintext
crypt(data, 'fooz', 'bf')
crypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

### F.25.5. Random-Data Functions

**gen_random_bytes(count integer) returns bytea**

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

**gen_random_uuid() returns uuid**

Returns a version 4 (random) UUID.

### F.25.6. Notes

#### F.25.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main PostgreSQL configure script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with zlib, PGP encryption functions are able to compress data before encrypting.

When compiled with OpenSSL, there will be more algorithms available. Also public-key encryption functions will be faster as OpenSSL has more optimized BIGNUM functions.

#### Table F-20. Summary of Functionality with and without OpenSSL

Notes:

1. SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, `pgcrypto` will use built-in code.
2. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.
3. AES is included in OpenSSL since version 0.9.7. For older versions, `pgcrypto` will use built-in code.

F.25.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.25.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist side-channel attacks\(^5\). For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

**F.26. pg_freespacemap**

The pg_freespacemap module provides a means for examining the free space map (FSM). It provides a function called pg_freespace, or two overloaded functions, to be precise. The functions
show the value recorded in the free space map for a given page, or for all pages in the relation.
By default public access is revoked from the functions, just in case there are security issues lurking.

F.26.1. Functions

pg_freespace(rel regclass IN, blkno bigint IN) returns int2

Returns the amount of free space on the page of the relation, specified by blkno, according to the FSM.

pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)

Displays the amount of free space on each page of the relation, according to the FSM. A set of (blkno bigint, avail int2) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They’re rounded to precision of 1/256th of \( \text{BLCKSZ} \) (32 bytes with default \( \text{BLCKSZ} \)), and they’re not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

Note: The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

F.26.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
blkno | avail
-------+-------
  0 | 0
  1 | 0
  2 | 32
  3 | 704
  4 | 704
  5 | 704
  6 | 704
  7 | 1216
  8 | 704
  9 | 704
 10 | 704
 11 | 704
 12 | 704
 13 | 704
 14 | 704
 15 | 704
 16 | 704
 17 | 704
 18 | 704
 19 | 3648
(20 rows)
```

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
2436
```
F.26.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.27. pg_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the PostgreSQL buffer cache.

F.27.1. Functions

```sql
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',
            first_block int8 default null,
            last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by PostgreSQL when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

F.27.2. Author

Robert Haas <rhaas@postgresql.org>
F.28. pgrowlocks

The pgrowlocks module provides a function to show row locking information for a specified table.

F.28.1. Overview

pgrowlocks(text) returns setof record

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in Table F-21.

Table F-21. pgrowlocks Output Columns

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locked_row</td>
<td>tid</td>
<td>Tuple ID (TID) of locked row</td>
</tr>
<tr>
<td>locker</td>
<td>xid</td>
<td>Transaction ID of locker, or multixact ID if multitransaction</td>
</tr>
<tr>
<td>multi</td>
<td>boolean</td>
<td>True if locker is a multitransaction</td>
</tr>
<tr>
<td>xids</td>
<td>xid[]</td>
<td>Transaction IDs of lockers (more than one if multitransaction)</td>
</tr>
<tr>
<td>modes</td>
<td>text[]</td>
<td>Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.</td>
</tr>
<tr>
<td>pids</td>
<td>integer[]</td>
<td>Process IDs of locking backends (more than one if multitransaction)</td>
</tr>
</tbody>
</table>

pgrowlocks takes AccessShareLock for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If the table as a whole is exclusive-locked by someone else, pgrowlocks will be blocked.
2. pgrowlocks is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

pgrowlocks does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.
F.28.2. Sample Output

```sql
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
------------------------------------------
(0,1) | 609 | f | {609} |{"For Share"} | {3161}
(0,2) | 609 | f | {609} |{"For Share"} | {3161}
(0,3) | 607 | f | {607} |{"For Update"} | {3107}
(0,4) | 607 | f | {607} |{"For Update"} | {3107}
```

Tatsuo Ishii

F.29. pg_stat Statements

The pg_stat_statements module provides a means for tracking execution statistics of all SQL statements executed by a server.

The module must be loaded by adding pg_stat_statements to shared_preload_libraries in postgresql.conf, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When pg_stat_statements is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, pg_stat_statements, and the utility functions pg_stat_statements_reset and pg_stat_statements. These are not available globally but can be enabled for a specific database with CREATE EXTENSION pg_stat_statements.

F.29.1. The pg_stat_statements View

The statistics gathered by the module are made available via a view named pg_stat_statements. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in Table F-22.

Table F-22. pg_stat_statements Columns

</tbody>
</table>

For security reasons, non-superusers are not allowed to see the SQL text or queryid of queries executed by other users. They can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, SELECT, INSERT, UPDATE, and DELETE) are combined into a single pg_stat_statements entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant’s value has been ignored for purposes of matching the query to other queries, the constant is replaced by ? in the pg_stat_statements display. The rest of the query text is that of the first query that had the particular queryid hash value associated with the pg_stat_statements entry.

In some cases, queries with visibly different texts might get merged into a single pg_stat_statements entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the queryid hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different search_path settings.

Consumers of pg_stat_statements may wish to use queryid (perhaps in combination with dbid and userid) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the queryid hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, pg_stat_statements will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that queryid will...
be stable across major versions of PostgreSQL.

As a rule of thumb, \texttt{queryid} values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical \texttt{queryid} values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so \texttt{queryid} will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, \texttt{pg_stat_statements} may choose to discard the query texts, whereupon all existing entries in the \texttt{pg_stat_statements} view will show null query fields, though the statistics associated with each \texttt{queryid} are preserved. If this happens, consider reducing \texttt{pg_stat_statements.max} to prevent recurrences.

### F.29.2. Functions

\texttt{pg_stat_statements_reset()} returns \texttt{void}

\begin{verbatim}
    pg_stat_statements_reset() discards all statistics gathered so far by
    pg_stat_statements. By default, this function can only be executed by superusers.
\end{verbatim}

\texttt{pg_stat_statements(showtext boolean)} returns \texttt{setof record}

The \texttt{pg_stat_statements} view is defined in terms of a function also named \texttt{pg_stat_statements}. It is possible for clients to call the \texttt{pg_stat_statements} function directly, and by specifying \texttt{showtext := false} have query text be omitted (that is, the \texttt{OUT} argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all \texttt{pg_stat_statements} itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the \texttt{pg_stat_statements} data.

### F.29.3. Configuration Parameters

\texttt{pg_stat_statements.max(integer)}

\begin{verbatim}
    pg_stat_statements.max is the maximum number of statements tracked by the module (i.e.,
    the maximum number of rows in the pg_stat_statements view). If more distinct statements
    than that are observed, information about the least-executed statements is discarded. The default
    value is 5000. This parameter can only be set at server start.
\end{verbatim}

\texttt{pg_stat_statements.track(enum)}

\begin{verbatim}
    pg_stat_statements.track controls which statements are counted by the module. Specify
    top to track top-level statements (those issued directly by clients), all to also track nested
    statements (such as statements invoked within functions), or none to disable statement statistics
    collection. The default value is top. Only superusers can change this setting.
\end{verbatim}
pg_stat_statements.track_utility (boolean)

pg_stat_statements.track_utility controls whether utility commands are tracked by
the module. Utility commands are all those other than SELECT, INSERT, UPDATE and DELETE.
The default value is on. Only superusers can change this setting.

pg_stat_statements.save (boolean)

pg_stat_statements.save specifies whether to save statement statistics across server shut-
downs. If it is off then statistics are not saved at shutdown nor reloaded at server start. The
default value is on. This parameter can only be set in the postgresql.conf file or on the
server command line.

The module requires additional shared memory proportional to pg_stat_statements.max.
Note that this memory is consumed whenever the module is loaded, even if
pg_stat_statements.track is set to none.

These parameters must be set in postgresql.conf. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'
pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

F.29.4. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# "
x

F.29.5. Authors
Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.30. pgstattuple
The pgstattuple module provides various functions to obtain tuple-level statistics.

F.30.1. Functions

pgstattuple(regclass) returns record

pgstattuple returns a relation’s physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation’s name (optionally schema-qualified) or OID. For example:

test=> SELECT * FROM pgstattuple(‘pg_catalog.pg_proc’);
-[- RECORD 1 ]------------------
table_len | 458752
tuple_count | 1470
tuple_len | 438896
tuple_percent | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space | 8932
free_percent | 1.95

The output columns are described in Table F-23.

Table F-23. pgstattuple Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes</td>
</tr>
<tr>
<td>tuple_count</td>
<td>bigint</td>
<td>Number of live tuples</td>
</tr>
<tr>
<td>tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes</td>
</tr>
</tbody>
</table>
Appendix F: Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>free_space</td>
<td>bigint</td>
<td>Total free space in bytes</td>
</tr>
<tr>
<td>free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

**Note:** The table_len will always be greater than the sum of the tuple_len, dead_tuple_len and free_space. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```sql
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
```

```
- [ RECORD 1 ]--------+
version | 2
 tree_level | 0
 index_size | 16384
 root_block_no | 1
 internal_pages | 0
 leaf_pages | 1
 empty_pages | 0
 deleted_pages | 0
 avg_leaf_density | 54.27
 leaf_fragmentation | 0
```

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>B-tree version number</td>
</tr>
<tr>
<td>tree_level</td>
<td>integer</td>
<td>Tree level of the root page</td>
</tr>
<tr>
<td>index_size</td>
<td>bigint</td>
<td>Total index size in bytes</td>
</tr>
<tr>
<td>root_block_no</td>
<td>bigint</td>
<td>Location of root page (zero if none)</td>
</tr>
<tr>
<td>internal_pages</td>
<td>bigint</td>
<td>Number of “internal” (upper-level) pages</td>
</tr>
<tr>
<td>leaf_pages</td>
<td>bigint</td>
<td>Number of leaf pages</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>empty_pages</td>
<td>bigint</td>
<td>Number of empty pages</td>
</tr>
<tr>
<td>deleted_pages</td>
<td>bigint</td>
<td>Number of deleted pages</td>
</tr>
<tr>
<td>avg_leaf_density</td>
<td>float8</td>
<td>Average density of leaf pages</td>
</tr>
<tr>
<td>leaf_fragmentation</td>
<td>float8</td>
<td>Leaf page fragmentation</td>
</tr>
</tbody>
</table>

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages + leaf_pages + empty_pages + deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```sql
SELECT * FROM pgstatginindex('test_gin_index');
```

- [ RECORD 1 ]--------
  - version | 1
  - pending_pages | 0
  - pending_tuples | 0

The output columns are:

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>integer</td>
<td>GIN version number</td>
</tr>
<tr>
<td>pending_pages</td>
<td>integer</td>
<td>Number of pages in the pending list</td>
</tr>
<tr>
<td>pending_tuples</td>
<td>bigint</td>
<td>Number of tuples in the pending list</td>
</tr>
</tbody>
</table>

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation’s name or OID. For example:

```sql
SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc::regclass');
```

- [ RECORD 1 ]--------
  - table_len | 573440
  - scanned_percent | 2
Appendix F. Additional Supplied Modules

approx_tuple_count | 2740
approx_tuple_len | 561210
approx_tuple_percent | 97.87
dead_tuple_count | 0
dead_tuple_len | 0
dead_tuple_percent | 0
approx_free_space | 11996
approx_free_percent | 2.09

The output columns are described in Table F-24.

Whereas pgstattuple always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, pgstattuple_approx tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that VACUUM estimates pg_class.reltuples).

Table F-24. pgstattuple_approx Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_len</td>
<td>bigint</td>
<td>Physical relation length in bytes (exact)</td>
</tr>
<tr>
<td>scanned_percent</td>
<td>float8</td>
<td>Percentage of table scanned</td>
</tr>
<tr>
<td>approx_tuple_count</td>
<td>bigint</td>
<td>Number of live tuples (estimated)</td>
</tr>
<tr>
<td>approx_tuple_len</td>
<td>bigint</td>
<td>Total length of live tuples in bytes (estimated)</td>
</tr>
<tr>
<td>approx_tuple_percent</td>
<td>float8</td>
<td>Percentage of live tuples</td>
</tr>
<tr>
<td>dead_tuple_count</td>
<td>bigint</td>
<td>Number of dead tuples (exact)</td>
</tr>
<tr>
<td>dead_tuple_len</td>
<td>bigint</td>
<td>Total length of dead tuples in bytes (exact)</td>
</tr>
<tr>
<td>dead_tuple_percent</td>
<td>float8</td>
<td>Percentage of dead tuples</td>
</tr>
<tr>
<td>approx_free_space</td>
<td>bigint</td>
<td>Total free space in bytes (estimated)</td>
</tr>
<tr>
<td>approx_free_percent</td>
<td>float8</td>
<td>Percentage of free space</td>
</tr>
</tbody>
</table>

In the above output, the free space figures may not match the pgstattuple output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.30.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen
F.31. pg_trgm

The pg_trgm module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

F.31.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

**Note:** pg_trgm ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is "c", "ca", "cat", and "at". The set of trigrams in the string "foo|bar" is "f", "fo", "foo", "oo ", " b", " ba", "bar", and "ar ".

F.31.2. Functions and Operators

The functions provided by the pg_trgm module are shown in Table F-25, the operators in Table F-26.

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>similarity(text, text)</td>
<td>real</td>
<td>Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).</td>
</tr>
<tr>
<td>show_trgm(text)</td>
<td>text[]</td>
<td>Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)</td>
</tr>
<tr>
<td>word_similarity(text, text)</td>
<td>real</td>
<td>Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.</td>
</tr>
</tbody>
</table>
### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show_limit()</code></td>
<td>real</td>
<td>Returns the current similarity threshold used by the % operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example (deprecated).</td>
</tr>
<tr>
<td><code>set_limit(real)</code></td>
<td>real</td>
<td>Sets the current similarity threshold that is used by the % operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in (deprecated).</td>
</tr>
</tbody>
</table>

Consider the following example:

```sql
# SELECT word_similarity('word', 'two words');
word_similarity
-----------------
0.8
(1 row)
```

In the first string, the set of trigrams is {"w", "wo", "ord", "wor", "rd"}. In the second string, the ordered set of trigrams is {"t", "tw", "two", "wo", "w", "wo", "wor", "ord", "rds", "ds"}. The most similar extent of an ordered set of trigrams in the second string is {"w", "wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

### Table F-26. pg_trgm Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text % text</code></td>
<td>boolean</td>
<td>Returns true if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code>.</td>
</tr>
<tr>
<td><code>text &lt;# text</code></td>
<td>boolean</td>
<td>Returns true if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.</td>
</tr>
</tbody>
</table>
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>Operator</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text %&gt; text</code></td>
<td>boolean</td>
<td>Commutator of the <code>&lt;%</code> operator.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code></td>
<td>real</td>
<td>Returns the “distance” between the arguments, that is one minus the similarity() value.</td>
</tr>
<tr>
<td><code>text &lt;-&gt; text</code></td>
<td>real</td>
<td>Returns the “distance” between the arguments, that is one minus the word_similarity() value.</td>
</tr>
<tr>
<td><code>text &lt;-&gt;&gt;&gt; text</code></td>
<td>real</td>
<td>Commutator of the <code>&lt;&lt;&lt;-</code> operator.</td>
</tr>
</tbody>
</table>

### F.31.3. GUC Parameters

- **pg_trgm.similarity_threshold** (real)
  
  Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

- **pg_trgm.word_similarity_threshold** (real)
  
  Sets the current word similarity threshold that is used by `<%` and `>%` operators. The threshold must be between 0 and 1 (default is 0.6).

### F.31.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```sql
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```sql
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```sql
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```
This will return all values in the text column that are sufficiently similar to \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

\begin{verbatim}
SELECT t, t <-> 'word' AS dist 
FROM test_trgm 
ORDER BY dist LIMIT 10;
\end{verbatim}

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the \textit{t} column for word similarity. For example:

\begin{verbatim}
SELECT t, word_similarity('word', t) AS sml 
FROM test_trgm 
WHERE 'word' % t 
ORDER BY sml DESC, t;
\end{verbatim}

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of \textit{word}, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

\begin{verbatim}
SELECT t, 'word' <-> t AS dist 
FROM test_trgm 
ORDER BY dist LIMIT 10;
\end{verbatim}

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for \texttt{LIKE} and \texttt{ILIKE}, for example

\begin{verbatim}
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
\end{verbatim}

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (\texttt{~} and \texttt{~*} operators), for example

\begin{verbatim}
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
\end{verbatim}

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both \texttt{LIKE} and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.
F.31.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM ts_stat('SELECT to_tsvector("simple", bodytext) FROM documents');
```

where documents is a table that has a text field bodytext that we wish to search. The reason for using the simple configuration with the to_tsvector function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a SELECT query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

**Note:** Since the words table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.32. pg_visibility

The pg_visibility module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.
Appendix F. Additional Supplied Modules

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header’s `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page’s all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation’s data blocks rather than only the (much smaller) visibility map. Functions that check the relation’s data blocks are similarly expensive.

F.32.1. Functions

```sql
pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean) returns record

  Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns record

  Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean) returns setof record

  Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean) returns setof record

  Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint) returns record

  Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

pg_check_frozen(relation regclass, t_ctid OUT tid) returns setof tid

  Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

pg_check_visible(relation regclass, t_ctid OUT tid) returns setof tid

  Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.
```
pg_truncate_visibility_map(relation regclass) returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first VACUUM executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers.

F.32.2. Author

Robert Haas <rhaas@postgresql.org>

F.33. postgres_fdw

The postgres_fdw module provides the foreign-data wrapper postgres_fdw, which can be used to access data stored in external PostgreSQL servers.

The functionality provided by this module overlaps substantially with the functionality of the older dblink module. But postgres_fdw provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using postgres_fdw:

1. Install the postgres_fdw extension using CREATE EXTENSION.
2. Create a foreign server object, using CREATE SERVER, to represent each remote database you want to connect to. Specify connection information, except user and password, as options of the server object.
3. Create a user mapping, using CREATE USER MAPPING, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as user and password options of the user mapping.
4. Create a foreign table, using CREATE FOREIGN TABLE or IMPORT FOREIGN SCHEMA, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table’s, if you specify the correct remote names as options of the foreign table object.

Now you need only SELECT from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using INSERT, UPDATE, or DELETE. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that postgres_fdw currently lacks support for INSERT statements with an ON CONFLICT DO UPDATE clause. However, the ON CONFLICT DO NOTHING clause is supported, provided a unique index inference specification is omitted.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although postgres_fdw is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting WHERE clauses slightly differently from the local server.
Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

**F.33.1. FDW Options of postgres_fdw**

**F.33.1.1. Connection Options**

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that libpq accepts in connection strings, as described in Section 32.1.2, except that these options are not allowed:

- `user` and `password` (specify these in a user mapping, instead)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

**F.33.1.2. Object Name Options**

These options can be used to control the names used in SQL statements sent to the remote PostgreSQL server. These options are needed when a foreign table is created with names different from the underlying remote table’s names.

- **schema_name**
  
  This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table’s schema is used.

- **table_name**
  
  This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table’s name is used.

- **column_name**
  
  This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column’s name is used.

**F.33.1.3. Cost Estimation Options**

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:
Appendix F. Additional Supplied Modules

use_remote_estimate

This option, which can be specified for a foreign table or a foreign server, controls whether \texttt{postgres_fdw} issues remote \texttt{EXPLAIN} commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is \texttt{false}.

\texttt{fdw\_startup\_cost}

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is \texttt{100}.

\texttt{fdw\_tuple\_cost}

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is \texttt{0.01}.

When \texttt{use\_remote\_estimate} is \texttt{true}, \texttt{postgres_fdw} obtains row count and cost estimates from the remote server and then adds \texttt{fdw\_startup\_cost} and \texttt{fdw\_tuple\_cost} to the cost estimates. When \texttt{use\_remote\_estimate} is \texttt{false}, \texttt{postgres_fdw} performs local row count and cost estimation and then adds \texttt{fdw\_startup\_cost} and \texttt{fdw\_tuple\_cost} to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table’s statistics are available. Running \texttt{ANALYZE} on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

\textbf{F.33.1.4. Remote Execution Options}

By default, only \texttt{WHERE} clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such \texttt{WHERE} clauses for remote execution. This behavior can be controlled using the following option:

\texttt{extensions}

This option is a comma-separated list of names of PostgreSQL extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the \texttt{extensions} option, \textit{it is the user’s responsibility} that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

\texttt{fetch\_size}

This option specifies the number of rows \texttt{postgres_fdw} should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is \texttt{100}. 

2456
F.33.1.5. Updatability Options

By default all foreign tables using postgres_fdw are assumed to be updatable. This may be overridden using the following option:

```
updatable
```

This option controls whether postgres_fdw allows foreign tables to be modified using INSERT, UPDATE and DELETE commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is true.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the information_schema views will report a postgres_fdw foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.33.1.6. Importing Options

postgres_fdw is able to import foreign table definitions using IMPORT FOREIGN SCHEMA. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the IMPORT FOREIGN SCHEMA command):

```
import_collate
```

This option controls whether column COLLATE options are included in the definitions of foreign tables imported from a foreign server. The default is true. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it’s running on a different operating system.

```
import_default
```

This option controls whether column DEFAULT expressions are included in the definitions of foreign tables imported from a foreign server. The default is false. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; nextval() is a common source of problems. The IMPORT will fail altogether if an imported default expression uses a function or operator that does not exist locally.

```
import_not_null
```

This option controls whether column NOT NULL constraints are included in the definitions of foreign tables imported from a foreign server. The default is true.

Note that constraints other than NOT NULL will never be imported from the remote tables. Although PostgreSQL does support CHECK constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a CHECK constraint could lead to hard-to-detect errors in query optimization. So if you wish to import CHECK constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of CHECK constraints on foreign tables, see CREATE FOREIGN TABLE.
F.33.2. Connection Management

postgres_fdw establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

F.33.3. Transaction Management

During a query that references any remote tables on a foreign server, postgres_fdw opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses SERIALIZABLE isolation level when the local transaction has SERIALIZABLE isolation level; otherwise it uses REPEATABLE READ isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses SERIALIZABLE or REPEATABLE READ isolation level, but it might be surprising for a READ COMMITTED local transaction. A future PostgreSQL release might modify these rules.

F.33.4. Remote Query Optimization

postgres_fdw attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query WHERE clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, WHERE clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that’s listed in the foreign server’s extensions option. Operators and functions in such clauses must be IMMUTABLE as well. For an UPDATE or DELETE query, postgres_fdw attempts to optimize the query execution by sending the whole query to the remote server if there are no query WHERE clauses that cannot be sent to the remote server, no local joins for the query, no row-level local BEFORE or AFTER triggers on the target table, and no CHECK OPTION constraints from parent views. In UPDATE, expressions to assign to target columns must use only built-in data types, IMMUTABLE operators, or IMMUTABLE functions, to reduce the risk of misexecution of the query.

When postgres_fdw encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the JOIN clauses, it takes the same precautions as mentioned above for the WHERE clauses.

The query that is actually sent to the remote server for execution can be examined using EXPLAIN VERBOSE.

F.33.5. Remote Query Execution Environment

In the remote sessions opened by postgres_fdw, the search_path parameter is set to just pg_catalog, so that only built-in objects are visible without schema qualification. This is not an
Appendix F. Additional Supplied Modules

issue for queries generated by postgres_fdw itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach SET search_path options (see CREATE FUNCTION) to such functions to establish their expected search path environment.

postgres_fdw likewise establishes remote session settings for the parameters TimeZone, DateStyle, IntervalStyle, and extra_float_digits. These are less likely to be problematic than search_path, but can be handled with function SET options if the need arises.

It is not recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause postgres_fdw to malfunction.

F.33.6. Cross-Version Compatibility

postgres_fdw can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that postgres_fdw generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a WHERE clause for a foreign table. Thus, a built-in function that was added since the remote server’s release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-SELECT with OFFSET 0 as an optimization fence, and placing the problematic function or operator outside the sub-SELECT.

F.33.7. Examples

Here is an example of creating a foreign table with postgres_fdw. First install the extension:

```sql
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using CREATE SERVER. In this example we wish to connect to a PostgreSQL server on host 192.83.123.89 listening on port 5432. The database to which the connection is made is named foreign_db on the remote server:

```sql
CREATE SERVER foreign_server
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with CREATE USER MAPPING, is needed as well to identify the role that will be used on the remote server:

```sql
CREATE USER MAPPING FOR local_user
SERVER foreign_server
OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with CREATE FOREIGN TABLE. In this example we wish to access the table named some_schema.some_table on the remote server. The local name for it will be foreign_table:

```sql
CREATE FOREIGN TABLE foreign_table
ASYNC
ON engage
USING postgres_fdw
FOREIGN DATA WRAPPER postgres_fdw
OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db', schema 'some_schema', table 'some_table');
```
CREATE FOREIGN TABLE foreign_table (  id integer NOT NULL,  data text )  
SERVER foreign_server  
OPTIONS (schema_name 'some_schema', table_name 'some_table');

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of `IMPORT FOREIGN SCHEMA` is preferable to constructing foreign table definitions manually.

F.33.8. Author

Shigeru Hanada <shigeru.hanada@gmail.com>

F.34. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

F.34.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
  pH
--
  6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.
Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
pH
-------------
6.25 .. 6.50
(1 row)
```

### F.34.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (.. or ...). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (<, > or ~) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) Table F-27 gives an overview of allowed representations; Table F-28 shows some examples.

In Table F-27, x, y, and delta denote floating-point numbers. x and y, but not delta, can be preceded by a certainty indicator.

<table>
<thead>
<tr>
<th>x</th>
<th>Single value (zero-length interval)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x .. y</td>
<td>Interval from x to y</td>
</tr>
<tr>
<td>x (+-) delta</td>
<td>Interval from x - delta to x + delta</td>
</tr>
<tr>
<td>x ..</td>
<td>Open interval with lower bound x</td>
</tr>
<tr>
<td>.. x</td>
<td>Open interval with upper bound x</td>
</tr>
</tbody>
</table>

#### Table F-27. seg External Representations

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>Creates a zero-length segment (a point, if you will)</td>
</tr>
<tr>
<td>~5.0</td>
<td>Creates a zero-length segment and records ~ in the data. ~ is ignored by seg operations, but is preserved as a comment.</td>
</tr>
<tr>
<td>&lt;5.0</td>
<td>Creates a point at 5.0. &lt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>&gt;5.0</td>
<td>Creates a point at 5.0. &gt; is ignored but is preserved as a comment.</td>
</tr>
<tr>
<td>5(+-)0.3</td>
<td>Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn’t preserved.</td>
</tr>
<tr>
<td>50 ..</td>
<td>Everything that is greater than or equal to 50</td>
</tr>
<tr>
<td>.. 0</td>
<td>Everything that is less than or equal to 0</td>
</tr>
<tr>
<td>1.5e-2 .. 2E-2</td>
<td>Creates an interval 0.015 .. 0.02</td>
</tr>
</tbody>
</table>
Appendix F. Additional Supplied Modules

1...2

The same as 1...2, or 1..2, or 1..2

(spaces around the range operator are ignored)

Because ... is widely used in data sources, it is allowed as an alternative spelling of ... Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in 0...23 is meant to be 23 or 0.23. This is resolved by requiring at least one digit before the decimal point in all numbers in seg input.

As a sanity check, seg rejects intervals with the lower bound greater than the upper, for example 5..2.

F.34.3. Precision

seg values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns 0.00, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value 0.0067 is considered to have just 2 significant digits.

F.34.4. Usage

The seg module includes a GiST index operator class for seg values. The operators supported by the GiST operator class are shown in Table F-29.

Table F-29. Seg GiST Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[a, b] &lt;&lt; [c, d]</td>
<td>[a, b] is entirely to the left of [c, d]. That is, [a, b] &lt;&lt; [c, d] is true if b &lt; c and false otherwise.</td>
</tr>
<tr>
<td>[a, b] &gt;&gt; [c, d]</td>
<td>[a, b] is entirely to the right of [c, d]. That is, [a, b] &gt;&gt; [c, d] is true if a &gt; d and false otherwise.</td>
</tr>
<tr>
<td>[a, b] &amp;&lt; [c, d]</td>
<td>Overlaps or is left of — This might be better read as “does not extend to right of”. It is true when b &lt;= d.</td>
</tr>
<tr>
<td>[a, b] &amp;&gt; [c, d]</td>
<td>Overlaps or is right of — This might be better read as “does not extend to left of”. It is true when a &gt;= c.</td>
</tr>
<tr>
<td>[a, b] = [c, d]</td>
<td>Same as — The segments [a, b] and [c, d] are identical, that is, a = c and b = d.</td>
</tr>
<tr>
<td>[a, b] @ [c, d]</td>
<td>The segments [a, b] and [c, d] overlap.</td>
</tr>
<tr>
<td>[a, b] @&gt; [c, d]</td>
<td>The segment [a, b] contains the segment [c, d], that is, a &lt;= c and b &gt;= d.</td>
</tr>
<tr>
<td>[a, b] @&lt; [c, d]</td>
<td>The segment [a, b] is contained in [c, d], that is, a &gt;= c and b &lt;= d.</td>
</tr>
</tbody>
</table>

(Before PostgreSQL 8.2, the containment operators @> and @< were respectively called @ and ~. 

2462
These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

The standard B-tree operators are also provided, for example

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[a, b] &lt; [c, d]</td>
<td>Less than</td>
</tr>
<tr>
<td>[a, b] &gt; [c, d]</td>
<td>Greater than</td>
</tr>
</tbody>
</table>

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use ORDER BY with this type.

**F.34.5. Notes**

For examples of usage, see the regression test sql/seg.sql.

The mechanism that converts (+-) to regular ranges isn’t completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```sql
postgres=\$> select '10(+-)1':seg as seg;
seg
---------
9.0 .. 11 -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the seg column; see the script sort-segments.pl for an example.

**F.34.6. Credits**

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (http://db.cs.berkeley.edu/jmh/) for elucidating the gist of the GiST (http://gist.cs.berkeley.edu/). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

**F.35. sepgsql**

sepgsql is a loadable module that supports label-based mandatory access control (MAC) based on SELinux security policy.
Appendix F. Additional Supplied Modules

Warning
The current implementation has significant limitations, and does not enforce mandatory access control for all actions. See Section F.35.7.

F.35.1. Overview

This module integrates with SELinux to provide an additional layer of security checking above and beyond what is normally provided by PostgreSQL. From the perspective of SELinux, this module allows PostgreSQL to function as a user-space object manager. Each table or function access initiated by a DML query will be checked against the system security policy. This check is in addition to the usual SQL permissions checking performed by PostgreSQL.

SELinux access control decisions are made using security labels, which are represented by strings such as system_u:object_r:sepgsql_table_t:s0. Each access control decision involves two labels: the label of the subject attempting to perform the action, and the label of the object on which the operation is to be performed. Since these labels can be applied to any sort of object, access control decisions for objects stored within the database can be (and, with this module, are) subjected to the same general criteria used for objects of any other type, such as files. This design is intended to allow a centralized security policy to protect information assets independent of the particulars of how those assets are stored.

The SECURITY LABEL statement allows assignment of a security label to a database object.

F.35.2. Installation

sepgsql can only be used on Linux 2.6.28 or higher with SELinux enabled. It is not available on any other platform. You will also need libselinux 2.1.10 or higher and selinux-policy 3.9.13 or higher (although some distributions may backport the necessary rules into older policy versions).

The sestatus command allows you to check the status of SELinux. A typical display is:

$ sestatus
SELinux status: enabled
SELinuxfs mount: /selinux
Current mode: enforcing
Mode from config file: enforcing
Policy version: 24
Policy from config file: targeted

If SELinux is disabled or not installed, you must set that product up first before installing this module.

To build this module, include the option --with-selinux in your PostgreSQL configure command. Be sure that the libselinux-devel RPM is installed at build time.

To use this module, you must include sepgsql in the shared_preload_libraries parameter in postgresql.conf. The module will not function correctly if loaded in any other manner. Once the module is loaded, you should execute sepgsql.sql in each database. This will install functions needed for security label management, and assign initial security labels.

Here is an example showing how to initialize a fresh database cluster with sepgsql functions and security labels installed. Adjust the paths shown as appropriate for your installation:

$ export PGDATA=/path/to/data/directory
$ initdb
Appendix F. Additional Supplied Modules

$ vi $PGDATA/postgresql.conf
change
#shared_preload_libraries = " # (change requires restart)
to
shared_preload_libraries = 'sepgsql' # (change requires restart)
$ for DBNAME in template0 template1 postgres; do
  postgres --single -F -c exit_on_error=true $DBNAME \
    </usr/local/pgsql/share/contrib/sepgsql.sql >/dev/null
done

Please note that you may see some or all of the following notifications depending on the particular versions you have of libselinux and selinux-policy:

/etc/selinux/targeted/contexts/sepgsql_contexts: line 33 has invalid object type db_blobs
/etc/selinux/targeted/contexts/sepgsql_contexts: line 36 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 37 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 38 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 39 has invalid object type db_language
/etc/selinux/targeted/contexts/sepgsql_contexts: line 40 has invalid object type db_language

These messages are harmless and should be ignored.

If the installation process completes without error, you can now start the server normally.

F.35.3. Regression Tests

Due to the nature of SELinux, running the regression tests for sepgsql requires several extra configuration steps, some of which must be done as root. The regression tests will not be run by an ordinary make check or make installcheck command; you must set up the configuration and then invoke the test script manually. The tests must be run in the contrib/sepgsql directory of a configured PostgreSQL build tree. Although they require a build tree, the tests are designed to be executed against an installed server, that is they are comparable to make installcheck not make check.

First, set up sepgsql in a working database according to the instructions in Section F.35.2. Note that the current operating system user must be able to connect to the database as superuser without password authentication.

Second, build and install the policy package for the regression test. The sepgsql-regtest policy is a special purpose policy package which provides a set of rules to be allowed during the regression tests. It should be built from the policy source file sepgsql-regtest.te, which is done using make with a Makefile supplied by SELinux. You will need to locate the appropriate Makefile on your system; the path shown below is only an example. Once built, install this policy package using the semodule command, which loads supplied policy packages into the kernel. If the package is correctly installed, semodule -l should list sepgsql-regtest as an available policy package:

$ cd .../contrib/sepgsql
$ make -f /usr/share/selinux/devel/Makefile
$ sudo semodule -u sepgsql-regtest.pp
$ sudo semodule -l | grep sepgsql
sepgsql-regtest 1.07

Third, turn on sepgsql_regression_test_mode. For security reasons, the rules in sepgsql-regtest are not enabled by default; the sepgsql_regression_test_mode parameter enables the rules needed to launch the regression tests. It can be turned on using the setsebool command:

$ setsebool -P sepgsql_regression_test_mode=true
$ sudo setsebool sepgsql_regression_test_mode on
$ getsebool sepgsql_regression_test_mode
sepgsql_regression_test_mode --> on

Fourth, verify your shell is operating in the unconfined_t domain:

$ id -Z
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023

See Section F.35.8 for details on adjusting your working domain, if necessary.

Finally, run the regression test script:

$ ./test_sepgsql

This script will attempt to verify that you have done all the configuration steps correctly, and then it will run the regression tests for the sepgsql module.

After completing the tests, it’s recommended you disable the sepgsql_regression_test_mode parameter:

$ sudo setsebool sepgsql_regression_test_mode off

You might prefer to remove the sepgsql-regtest policy entirely:

$ sudo semodule -r sepgsql-regtest

### F.35.4. GUC Parameters

**sepgsql.permissive** (boolean)

This parameter enables sepgsql to function in permissive mode, regardless of the system setting. The default is off. This parameter can only be set in the postgresql.conf file or on the server command line.

When this parameter is on, sepgsql functions in permissive mode, even if SELinux in general is working in enforcing mode. This parameter is primarily useful for testing purposes.

**sepgsql.debug_audit** (boolean)

This parameter enables the printing of audit messages regardless of the system policy settings. The default is off, which means that messages will be printed according to the system settings.

The security policy of SELinux also has rules to control whether or not particular accesses are logged. By default, access violations are logged, but allowed accesses are not.

This parameter forces all possible logging to be turned on, regardless of the system policy.

### F.35.5. Features

#### F.35.5.1. Controlled Object Classes

The security model of SELinux describes all the access control rules as relationships between a subject entity (typically, a client of the database) and an object entity (such as a database object), each of which is identified by a security label. If access to an unlabeled object is attempted, the object is treated as if it were assigned the label *unlabeled_t*. 

2466
Currently, sepgsql allows security labels to be assigned to schemas, tables, columns, sequences, views, and functions. When sepgsql is in use, security labels are automatically assigned to supported database objects at creation time. This label is called a default security label, and is decided according to the system security policy, which takes as input the creator’s label, the label assigned to the new object’s parent object and optionally name of the constructed object.

A new database object basically inherits the security label of the parent object, except when the security policy has special rules known as type-transition rules, in which case a different label may be applied. For schemas, the parent object is the current database; for tables, sequences, views, and functions, it is the containing schema; for columns, it is the containing table.

**F.35.5.2. DML Permissions**

For tables, `db_table:select`, `db_table:insert`, `db_table:update` or `db_table:delete` are checked for all the referenced target tables depending on the kind of statement; in addition, `db_table:select` is also checked for all the tables that contain columns referenced in the `WHERE` or `RETURNING` clause, as a data source for `UPDATE`, and so on.

Column-level permissions will also be checked for each referenced column. `db_column:select` is checked on not only the columns being read using `SELECT`, but those being referenced in other DML statements; `db_column:update` or `db_column:insert` will also be checked for columns being modified by `UPDATE` or `INSERT`.

For example, consider:

```
UPDATE t1 SET x = 2, y = md5sum(y) WHERE z = 100;
```

Here, `db_column:update` will be checked for `t1.x`, since it is being updated, `db_column:{select update}` will be checked for `t1.y`, since it is both updated and referenced, and `db_column:select` will be checked for `t1.z`, since it is only referenced. `db_table:{select update}` will also be checked at the table level.

For sequences, `db_sequence:get_value` is checked when we reference a sequence object using `SELECT`; however, note that we do not currently check permissions on execution of corresponding functions such as `lastval()`.

For views, `db_view:expand` will be checked, then any other required permissions will be checked on the objects being expanded from the view, individually.

For functions, `db_procedure:{execute}` will be checked when user tries to execute a function as a part of query, or using fast-path invocation. If this function is a trusted procedure, it also checks `db_procedure:{entrypoint}` permission to check whether it can perform as entry point of trusted procedure.

In order to access any schema object, `db_schema:search` permission is required on the containing schema. When an object is referenced without schema qualification, schemas on which this permission is not present will not be searched (just as if the user did not have `USAGE` privilege on the schema). If an explicit schema qualification is present, an error will occur if the user does not have the requisite permission on the named schema.

The client must be allowed to access all referenced tables and columns, even if they originated from views which were then expanded, so that we apply consistent access control rules independent of the manner in which the table contents are referenced.

The default database privilege system allows database superusers to modify system catalogs using DML commands, and reference or modify toast tables. These operations are prohibited when sepgsql is enabled.
F.35.5.3. DDL Permissions

SELinux defines several permissions to control common operations for each object type; such as creation, alter, drop and relabel of security label. In addition, several object types have special permissions to control their characteristic operations; such as addition or deletion of name entries within a particular schema.

Creating a new database object requires create permission. SELinux will grant or deny this permission based on the client’s security label and the proposed security label for the new object. In some cases, additional privileges are required:

- CREATE DATABASE additionally requires getattr permission for the source or template database.
- Creating a schema object additionally requires add_name permission on the parent schema.
- Creating a table additionally requires permission to create each individual table column, just as if each table column were a separate top-level object.
- Creating a function marked as LEAKPROOF additionally requires install permission. (This permission is also checked when LEAKPROOF is set for an existing function.)

When DROP command is executed, drop will be checked on the object being removed. Permissions will be also checked for objects dropped indirectly via CASCADE. Deletion of objects contained within a particular schema (tables, views, sequences and procedures) additionally requires remove_name on the schema.

When ALTER command is executed, setattr will be checked on the object being modified for each object types, except for subsidiary objects such as the indexes or triggers of a table, where permissions are instead checked on the parent object. In some cases, additional permissions are required:

- Moving an object to a new schema additionally requires remove_name permission on the old schema and add_name permission on the new one.
- Setting the LEAKPROOF attribute on a function requires install permission.
- Using SECURITY LABEL on an object additionally requires relabelfrom permission for the object in conjunction with its old security label and relabelto permission for the object in conjunction with its new security label. (In cases where multiple label providers are installed and the user tries to set a security label, but it is not managed by SELinux, only setattr should be checked here. This is currently not done due to implementation restrictions.)

F.35.5.4. Trusted Procedures

Trusted procedures are similar to security definer functions or setuid commands. SELinux provides a feature to allow trusted code to run using a security label different from that of the client, generally for the purpose of providing highly controlled access to sensitive data (e.g. rows might be omitted, or the precision of stored values might be reduced). Whether or not a function acts as a trusted procedure is controlled by its security label and the operating system security policy. For example:

```
postgres=# CREATE TABLE customer (    cid int primary key,
    cname text,
    credit text
);
CREATE TABLE
postgres=# SECURITY LABEL ON COLUMN customer.credit
```
Appendix F. Additional Supplied Modules

IS 'system_u:object_r:sepgsql_secret_table_t:s0';

postgres=# CREATE FUNCTION show_credit(int) RETURNS text AS 'SELECT regexp_replace(credit, "-\-[0-9]+\$", "-xxxx", "g") FROM customer WHERE cid = $1' LANGUAGE sql;

CREATE FUNCTION

postgres=# SECURITY LABEL ON FUNCTION show_credit(int) IS 'system_u:object_r:sepgsql_trusted_proc_exec_t:s0';

SECURITY LABEL

The above operations should be performed by an administrative user.

postgres=# SELECT * FROM customer;
ERROR: SELinux: security policy violation

postgres=# SELECT cid, cname, show_credit(cid) FROM customer;
cid | cname | show_credit
-----+--------+---------------------
 1 | taro | 1111-2222-3333-xxxx
 2 | hanako | 5555-6666-7777-xxxx
(2 rows)

In this case, a regular user cannot reference customer.credit directly, but a trusted procedure show_credit allows the user to print the credit card numbers of customers with some of the digits masked out.

F.35.5.5. Dynamic Domain Transitions

It is possible to use SELinux’s dynamic domain transition feature to switch the security label of the client process, the client domain, to a new context, if that is allowed by the security policy. The client domain needs the setcurrent permission and also dyntransition from the old to the new domain.

Dynamic domain transitions should be considered carefully, because they allow users to switch their label, and therefore their privileges, at their option, rather than (as in the case of a trusted procedure) as mandated by the system. Thus, the dyntransition permission is only considered safe when used to switch to a domain with a smaller set of privileges than the original one. For example:

regression=# select sepgsql_getcon();

sepgsql_getcon

---------------------
unconfined_u:unconfined_r:unconfined_t:s0-s0:c0.c1023
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4')

sepgsql_setcon

---------------------
t
(1 row)

regression=# SELECT sepgsql_setcon('unconfined_u:unconfined_r:unconfined_t:s0-s0:c1.c4')

ERROR: SELinux: security policy violation

In this example above we were allowed to switch from the larger MCS range c1.c1023 to the smaller range c1.c4, but switching back was denied.
A combination of dynamic domain transition and trusted procedure enables an interesting use case that fits the typical process life-cycle of connection pooling software. Even if your connection pooling software is not allowed to run most of SQL commands, you can allow it to switch the security label of the client using the `sepgsql_setcon()` function from within a trusted procedure; that should take some credential to authorize the request to switch the client label. After that, this session will have the privileges of the target user, rather than the connection pooler. The connection pooler can later revert the security label change by again using `sepgsql_setcon()` with `NULL` argument, again invoked from within a trusted procedure with appropriate permissions checks. The point here is that only the trusted procedure actually has permission to change the effective security label, and only does so when given proper credentials. Of course, for secure operation, the credential store (table, procedure definition, or whatever) must be protected from unauthorized access.

F.35.5.6. Miscellaneous
We reject the LOAD command across the board, because any module loaded could easily circumvent security policy enforcement.

F.35.6. Sepgsqsql Functions
Table F-30 shows the available functions.

**Table F-30. Sepgsqsql Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sepgsql_getcon()</code></td>
<td>Returns text, the client domain, the current security label of the client.</td>
</tr>
<tr>
<td><code>sepgsql_setcon(text)</code></td>
<td>Returns bool, switches the client domain of the current session to the new domain, if allowed by the security policy. It also accepts <code>NULL</code> input as a request to transition to the client’s original domain.</td>
</tr>
<tr>
<td><code>sepgsql_mcstrans_in(text)</code></td>

</tr>
<tr>
<td><code>sepgsql_restorecon(text)</code></td>
<td>Returns bool, sets up initial security labels for all objects within the current database. The argument may be <code>NULL</code>, or the name of a specfile to be used as alternative of the system default.</td>
</tr>
</tbody>
</table>

F.35.7. Limitations

Data Definition Language (DDL) Permissions

Due to implementation restrictions, some DDL operations do not check permissions.
Data Control Language (DCL) Permissions

Due to implementation restrictions, DCL operations do not check permissions.

Row-level access control

PostgreSQL supports row-level access, but sepgsql does not.

Covert channels

sepgsql does not try to hide the existence of a certain object, even if the user is not allowed to reference it. For example, we can infer the existence of an invisible object as a result of primary key conflicts, foreign key violations, and so on, even if we cannot obtain the contents of the object. The existence of a top secret table cannot be hidden; we only hope to conceal its contents.

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.36. spi

The spi module provides several workable examples of using the Server Programming Interface (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

---

F.36.1. *refint* — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table’s column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table’s column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked NOT NULL and should have a unique index.

There are examples in `refint.example`.

F.36.2. *timetravel* — Functions for Implementing Time Travel

Long ago, PostgreSQL had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of `abstime` type to store the date when a tuple was inserted (start_date) and changed/deleted (stop_date):

```
CREATE TABLE mytab (  
    ...  
    start_date abstime,  
    stop_date abstime  
    ...  
);
```

The columns can be named whatever you like, but in this discussion we’ll call them `start_date` and `stop_date`.

When a new row is inserted, `start_date` should normally be set to current time, and `stop_date` to `infinity`. The trigger will automatically substitute these values if the inserted data contains nulls in these columns. Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with `stop_date` equal to `infinity` are “valid now”, and can be modified. Tuples with a finite `stop_date` cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the `stop_date` in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. `Start_date` in this new tuple will be set to current time and `stop_date` to `infinity`.
A delete does not actually remove the tuple but only sets its stop_date to current time.

To query for tuples “valid now”, include stop_date = ‘infinity’ in the query’s WHERE condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on start_date and stop_date.

timetravel() is the general trigger function that supports this behavior. Create a BEFORE INSERT OR UPDATE OR DELETE trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the start_date and stop_date columns. Optionally, you can specify one to three more arguments, which must refer to columns of type text. The trigger will store the name of the current user into the first of these columns during INSERT, the second column during UPDATE, and the third during DELETE.

set_timetravel() allows you to turn time-travel on or off for a table. set_timetravel('mytab', 1) will turn TT ON for table mytab. set_timetravel('mytab', 0) will turn TT OFF for table mytab. In both cases the old status is reported. While TT is off, you can modify the start_date and stop_date columns freely. Note that the on/off status is local to the current database session — fresh sessions will always start out with TT ON for all tables.

get_timetravel() returns the TT state for a table without changing it.

There is an example in timetravel.example.

**F.36.3. autoinc — Functions for Autoincrementing Fields**

autoinc() is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: autoinc() will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a BEFORE INSERT (or optionally BEFORE INSERT OR UPDATE) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you’d like to update more than one autoincrementing column.)

There is an example in autoinc.example.

**F.36.4. insert_username — Functions for Tracking Who Changed a Table**

insert_username() is a trigger that stores the current user’s name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a BEFORE INSERT and/or UPDATE trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in insert_username.example.

**F.36.5. moddatetime — Functions for Tracking Last Modification Time**

moddatetime() is a trigger that stores the current time into a timestamp field. This can be useful for tracking the last modification time of a particular row within a table.
To use, create a BEFORE UPDATE trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type timestamp or timestamp with time zone.

There is an example in moddatetime.example.

F.37. sslinfo

The sslinfo module provides information about the SSL certificate that the current client provided when connecting to PostgreSQL. The module is useless (most functions will return NULL) if the current connection does not use SSL.

This extension won’t build at all unless the installation was configured with --with-openssl.

F.37.1. Functions Provided

ssl_is_used() returns boolean

Returns TRUE if current connection to server uses SSL, and FALSE otherwise.

ssl_version() returns text

Returns the name of the protocol used for the SSL connection (e.g. SSLv2, SSLv3, or TLSv1).

ssl_cipher() returns text

Returns the name of the cipher used for the SSL connection (e.g. DHE-RSA-AES256-SHA).

ssl_client_cert_present() returns boolean

Returns TRUE if current client has presented a valid SSL client certificate to the server, and FALSE otherwise. (The server might or might not be configured to require a client certificate.)

ssl_client_serial() returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

ssl_client_dn() returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like /CN=Somebody /C=Some country/O=Some organization.

ssl_issuer_dn() returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for ssl_client_dn.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.
Appendix F. Additional Supplied Modules

This function is really useful only if you have more than one trusted CA certificate in your server’s `root.crt` file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text) returns text`

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

- `commonName` (alias `CN`)
- `surname` (alias `SN`)
- `name`
- `givenName` (alias `GN`)
- `countryName` (alias `C`)
- `localityName` (alias `L`)
- `stateOrProvinceName` (alias `ST`)
- `organizationName` (alias `O`)
- `organizationUnitName` (alias `OU`)
- `title`
- `description`
- `initials`
- `postalCode`
- `streetAddress`
- `generationQualifier`
- `description`
- `dnQualifier`
- `x500UniqueIdentifier`
- `pseudonym`
- `role`
- `emailAddress`

All of these fields are optional, except `commonName`. It depends entirely on your CA’s policy which of them would be included and which wouldn’t. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text) returns text`

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info() returns setof record`

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.38. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

### F.38.1. Functions Provided

Table F-31 shows the functions provided by the `tablefunc` module.

**Table F-31. tablefunc Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>normal_rand(int numvals, float8 mean, float8 stddev)</code></td>
<td><code>setof float8</code></td>
<td>Produces a set of normally distributed random values</td>
</tr>
<tr>
<td><code>crosstab(text sql)</code></td>
<td><code>setof record</code></td>
<td>Produces a “pivot table” containing row names plus ( N ) value columns, where ( N ) is determined by the row type specified in the calling query</td>
</tr>
<tr>
<td><code>crosstabN(text sql)</code></td>
<td><code>setof table_crosstab_N</code></td>
<td>Produces a “pivot table” containing row names plus ( N ) value columns. <code>crosstab2</code>, <code>crosstab3</code>, and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below</td>
</tr>
<tr>
<td><code>crosstab(text source_sql, text category_sql)</code></td>
<td><code>setof record</code></td>
<td>Produces a “pivot table” with the value columns specified by a second query</td>
</tr>
<tr>
<td><code>crosstab(text sql, int N)</code></td>
<td><code>setof record</code></td>
<td>Obsolete version of <code>crosstab(text)</code>. The parameter ( N ) is now ignored, since the number of value columns is always determined by the calling query</td>
</tr>
<tr>
<td><code>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])</code></td>
<td><code>setof record</code></td>
<td>Produces a representation of a hierarchical tree structure</td>
</tr>
</tbody>
</table>

### F.38.1.1. normal_rand

The function `normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`
Appendix F. Additional Supplied Modules

normal_rand produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. mean is the mean of the normal distribution of values and stddev is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```sql
test=# SELECT * FROM normal_rand(1000, 5, 3);
```

```
<table>
<thead>
<tr>
<th>normal_rand</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.56556322244898</td>
</tr>
<tr>
<td>9.10040991424657</td>
</tr>
<tr>
<td>5.36957140345079</td>
</tr>
<tr>
<td>-0.369151492880995</td>
</tr>
<tr>
<td>0.283600703686639</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>4.82992125404908</td>
</tr>
<tr>
<td>9.71308014517282</td>
</tr>
<tr>
<td>2.49639286969028</td>
</tr>
</tbody>
</table>
```

1000 rows

F.38.1.2. crosstab(text)

crosstab(text sql)
crosstab(text sql, int N)

The crosstab function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1   val11
row1   val12
row1   val13
...
row2   val21
row2   val22
row2   val23
...
```

which we wish to display like

```
row1   val11   val12   val13   ...
row2   val21   val22   val23   ...
...
```

The crosstab function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The sql parameter is a SQL statement that produces the source set of data. This statement must return one row_name column, one category column, and one value column. N is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

```
row_name  cat  value
```
The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```
<== value columns ==>  
 row_name  category_1  category_2  
----------+------------+------------
 row1      val1       val2
 row2      val5       val6
```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by N `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output `value` columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it’s just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```sql
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT * FROM crosstab('select rowid, attribute, value from ct');
```
Appendix F. Additional Supplied Modules

where attribute = "att2" or attribute = "att3"
order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

row_name | category_1 | category_2 | category_3
----------+------------+------------+------------
test1     | val2       | val3       |             |
test2     | val6       | val7       |             |
(2 rows)

You can avoid always having to write out a FROM clause to define the output columns, by setting up a custom crosstab function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required FROM clause in a view definition.

Note: See also the \crosstabview command in psql, which provides functionality similar to crosstab().

F.38.1.3. crosstabN (text)

crosstabN(text sql)

The crosstabN functions are examples of how to set up custom wrappers for the general crosstab function, so that you need not write out column names and types in the calling SELECT query. The tablefunc module includes crosstab2, crosstab3, and crosstab4, whose output row types are defined as

CREATE TYPE tablefunc_crosstab_N AS {
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    .
    .
    category_N TEXT
};

Thus, these functions can be used directly when the input query produces row_name and value columns of type text, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general crosstab function.

For instance, the example given in the previous section would also work as

SELECT *
FROM crosstab3('select rowid, attribute, value
    from ct
    where attribute = "att2" or attribute = "att3"
    order by 1,2');

2479
These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one text parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` C function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

  ```sql
  CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
  );

  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
  RETURNS setof my_crosstab_float8_5_cols
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

  ```sql
  CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
  RETURNS setof record
  AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
  ```

### F.38.1.4. `crosstab(text, text)`

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn’t work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```sql
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```
### Appendix F. Additional Supplied Modules

<table>
<thead>
<tr>
<th>row_name</th>
<th>extra_col</th>
<th>cat</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat1</td>
<td>val1</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat2</td>
<td>val2</td>
</tr>
<tr>
<td>row1</td>
<td>extra1</td>
<td>cat4</td>
<td>val4</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat1</td>
<td>val5</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat2</td>
<td>val6</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat3</td>
<td>val7</td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>cat4</td>
<td>val8</td>
</tr>
</tbody>
</table>

**category_sql** is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. **category_sql** might be something like:

```sql
SELECT DISTINCT cat FROM foo ORDER BY 1;
```

<table>
<thead>
<tr>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
</tr>
<tr>
<td>cat2</td>
</tr>
<tr>
<td>cat3</td>
</tr>
<tr>
<td>cat4</td>
</tr>
</tbody>
</table>

The **crosstab** function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the **FROM clause** of the calling **SELECT** statement, for example:

```sql
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

<table>
<thead>
<tr>
<th>row_name</th>
<th>extra</th>
<th>cat1</th>
<th>cat2</th>
<th>cat3</th>
<th>cat4</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td>extra1</td>
<td>val1</td>
<td>val2</td>
<td>val4</td>
<td></td>
</tr>
<tr>
<td>row2</td>
<td>extra2</td>
<td>val5</td>
<td>val6</td>
<td>val7</td>
<td>val8</td>
</tr>
</tbody>
</table>

The **FROM clause** must define the proper number of output columns of the proper data types. If there are \( N \) columns in the **source_sql** query’s result, the first \( N-2 \) of them must match up with the first \( N-2 \) output columns. The remaining output columns must have the type of the last column of the **source_sql** query’s result, and there must be exactly as many of them as there are rows in the **category_sql** query’s result.

The **crosstab** function produces one output row for each consecutive group of input rows with the same **row_name** value. The output **row_name** column, plus any “extra” columns, are copied from the first row of the group. The output **value** columns are filled with the **value** fields from rows having matching **category** values. If a row’s **category** does not match any output of the **category_sql** query, its **value** is ignored. Output columns whose matching **category** is not present in any input row of the group are filled with nulls.
In practice the source_sql query should always specify ORDER BY 1 to ensure that values with the same row_name are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the category_sql query’s output matches the specified output column order.

Here are two complete examples:

```sql
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);

select * from crosstab(
    'select year, month, qty from sales order by 1',
    'select m from generate_series(1,12) m'
) as (year int, "Jan" int, "Feb" int, "Mar" int, "Apr" int, "May" int, "Jun" int, "Jul" int, "Aug" int, "Sep" int, "Oct" int, "Nov" int, "Dec" int );

<table>
<thead>
<tr>
<th>year</th>
<th>Jan</th>
<th>Feb</th>
<th>Mar</th>
<th>Apr</th>
<th>May</th>
<th>Jun</th>
<th>Jul</th>
<th>Aug</th>
<th>Sep</th>
<th>Oct</th>
<th>Nov</th>
<th>Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td>2007</td>
<td>1000</td>
<td>1500</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>500</td>
<td></td>
<td></td>
<td></td>
<td>1500</td>
<td>2000</td>
</tr>
<tr>
<td>2008</td>
<td>1000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab(
    'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
    'SELECT DISTINCT attribute FROM cth ORDER BY 1'
) AS (rowid text, rowdt timestamp, temperature int4,
```

</tr>
</tbody>
</table>

(2 rows)

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of crosstab is named crosstab_hash.

F.38.1.5. connectby

connectby(text relname, text keyid_fld, text parent_keyid_fld
  [, text orderby_fld ], text start_with, int max_depth
  [, text branch_delim ])

The connectby function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. connectby can display the sub-tree descending from any row.

Table F-32 explains the parameters.

Table F-32. connectby Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relname</td>
<td>Name of the source relation</td>
</tr>
<tr>
<td>keyid_fld</td>
<td>Name of the key field</td>
</tr>
<tr>
<td>parent_keyid_fld</td>
<td>Name of the parent-key field</td>
</tr>
<tr>
<td>orderby_fld</td>
<td>Name of the field to order siblings by (optional)</td>
</tr>
<tr>
<td>start_with</td>
<td>Key value of the row to start at</td>
</tr>
<tr>
<td>max_depth</td>
<td>Maximum depth to descend to, or zero for unlimited depth</td>
</tr>
<tr>
<td>branch_delim</td>
<td>String to separate keys with in branch output (optional)</td>
</tr>
</tbody>
</table>

The key and parent-key fields can be any data type, but they must be the same type. Note that the start_with value must be entered as a text string, regardless of the type of the key field.

The connectby function is declared to return setof record, so the actual names and types of the output columns must be defined in the FROM clause of the calling SELECT statement, for example:

  AS t(keyid text, parent_keyid text, level int, branch text, pos int);

The first two output columns are used for the current row’s key and its parent row’s key; they must match the type of the table’s key field. The third output column is the depth in the tree and must be of type integer. If a branch_delim parameter was given, the next output column is the branch display and must be of type text. Finally, if an orderby_fld parameter was given, the last output
Appendix F. Additional Supplied Modules

column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are
separated by the specified `branch_delim` string. If no branch display is wanted, omit both the
`branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to
specify which field to order siblings by. This field can be of any sortable data type. The output column
list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that
`connectby` generates internally. Therefore, include double quotes if the names are mixed-case or
contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may
incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default
value of `~` is used for recursion detection purposes.

Here is an example:

```sql
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);

INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);

-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);

F.38.2. Author

Joe Conway

F.39. tcn

The tcn module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an AFTER trigger FOR EACH ROW.

Only one parameter may be supplied to the function in a CREATE TRIGGER statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted tcn will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

test=# create table tcndata

test=# (a int not null,
Appendix F. Additional Supplied Modules

test(# b date not null,
test(# c text,
test(# primary key (a, b)
test(# )
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test-# after insert or update or delete on tcndata
test-# for each row execute procedure triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN

IN...
Appendix F. Additional Supplied Modules

F.41. tsearch2

The tsearch2 module provides backwards-compatible text search functionality for applications that used tsearch2 before text searching was integrated into core PostgreSQL in release 8.3.

F.41.1. Portability Issues

Although the built-in text search features were based on tsearch2 and are largely similar to it, there are numerous small differences that will create portability issues for existing applications:

- Some functions’ names were changed, for example rank to ts_rank. The replacement tsearch2 module provides aliases having the old names.
- The built-in text search data types and functions all exist within the system schema pg_catalog. In an installation using tsearch2, these objects would usually have been in the public schema, though some users chose to place them in a separate schema of their own. Explicitly schema-qualified references to the objects will therefore fail in either case. The replacement tsearch2 module provides alias objects that are stored in public (or another schema if necessary) so that such references will still work.
- There is no concept of a “current parser” or “current dictionary” in the built-in text search features, only of a current search configuration (set by the default_text_search_config parameter). While the current parser and current dictionary were used only by functions intended for debugging, this might still pose a porting obstacle in some cases. The replacement tsearch2 module emulates these additional state variables and provides backwards-compatible functions for setting and retrieving them.

There are some issues that are not addressed by the replacement tsearch2 module, and will therefore require application code changes in any case:

- The old tsearch2 trigger function allowed items in its argument list to be names of functions to be invoked on the text data before it was converted to tsvector format. This was removed as being a security hole, since it was not possible to guarantee that the function invoked was the one intended. The recommended approach if the data must be massaged before being indexed is to write a custom trigger that does the work for itself.
- Text search configuration information has been moved into core system catalogs that are noticeably different from the tables used by tsearch2. Any applications that examined or modified those tables will need adjustment.
- If an application used any custom text search configurations, those will need to be set up in the core catalogs using the new text search configuration SQL commands. The replacement tsearch2 module offers a little bit of support for this by making it possible to load an old set of tsearch2 configuration tables into PostgreSQL 8.3. (Without the module, it is not possible to load the configuration data because values in the regprocedure columns cannot be resolved to functions.) While those configuration tables won’t actually do anything, at least their contents will be available to be consulted while setting up an equivalent custom configuration in 8.3.
- The old reset_tsearch() and get_covers() functions are not supported.
- The replacement tsearch2 module does not define any alias operators, relying entirely on the built-in ones. This would only pose an issue if an application used explicitly schema-qualified operator names, which is very uncommon.
F.41.2. Converting a pre-8.3 Installation

The recommended way to update a pre-8.3 installation that uses tsearch2 is:

1. Make a dump from the old installation in the usual way, but be sure not to use \(-c (--clean)\) option of pg_dump or pg_dumpall.
2. In the new installation, create empty database(s) and install the replacement tsearch2 module into each database that will use text search. This must be done before loading the dump data! If your old installation had the tsearch2 objects in a schema other than public, be sure to adjust the CREATE EXTENSION command so that the replacement objects are created in that same schema.
3. Load the dump data. There will be quite a few errors reported due to failure to recreate the original tsearch2 objects. These errors can be ignored, but this means you cannot restore the dump in a single transaction (eg, you cannot use pg_restore’s \(-1\) switch).
4. Examine the contents of the restored tsearch2 configuration tables (pg_ts_cfg and so on), and create equivalent built-in text search configurations as needed. You may drop the old configuration tables once you’ve extracted all the useful information from them.
5. Test your application.

At a later time you may wish to rename application references to the alias text search objects, so that you can eventually uninstall the replacement tsearch2 module.

Tsearch2 Development Site http://www.sai.msu.su/~megera/postgres/gist/tsearch/V2/

F.42. tsm_system_rows

The tsm_system_rows module provides the table sampling method SYSTEM_ROWS, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in SYSTEM sampling method, SYSTEM_ROWS performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

SYSTEM_ROWS does not support the REPEATABLE clause.

F.42.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_ROWS. First install the extension:

CREATE EXTENSION tsm_system_rows;

Then you can use it in a SELECT command, for instance:

SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
Appendix F. Additional Supplied Modules

This command will return a sample of 100 rows from the table my_table (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.43. tsm_system_time

The tsm_system_time module provides the table sampling method SYSTEM_TIME, which can be used in the TABLESAMPLE clause of a SELECT command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in SYSTEM sampling method, SYSTEM_TIME performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

SYSTEM_TIME does not support the REPEATABLE clause.

F.43.1. Examples

Here is an example of selecting a sample of a table with SYSTEM_TIME. First install the extension:

CREATE EXTENSION tsm_system_time;

Then you can use it in a SELECT command, for instance:

SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);

This command will return as large a sample of my_table as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.44. unaccent

unaccent is a text search dictionary that removes accents (diacritic signs) from lexemes. It’s a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of unaccent cannot be used as a normalizing dictionary for the thesaurus dictionary.

F.44.1. Configuration

An unaccent dictionary accepts the following options:
• **RULES** is the base name of the file containing the list of translation rules. This file must be stored in `$SHAREDIR/tsearch_data/` (where `$SHAREDIR` means the PostgreSQL installation’s shared-data directory). Its name must end in `.rules` (which is not to be included in the **RULES** parameter).

The rules file has the following format:

• Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

```
Å A
Å A
Å A
Å A
Ä A
Å A
Æ AE
```

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

• Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.

• Actually, each “character” can be any string not containing whitespace, so unaccent dictionaries could be used for other sorts of substring substitutions besides diacritic removal.

• As with other PostgreSQL text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database’s encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$SHAREDIR/tsearch_data/` when the **unaccent** module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, Æ to AE).

### F.44.2. Usage

Installing the **unaccent** extension creates a text search template **unaccent** and a dictionary **unaccent** based on it. The **unaccent** dictionary has the default parameter setting **RULES**=`'unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
```

```
<table>
<thead>
<tr>
<th>ts_lexize</th>
</tr>
</thead>
<tbody>
<tr>
<td>{Hotel}</td>
</tr>
</tbody>
</table>
```

Here is an example showing how to insert the **unaccent** dictionary into a text search configuration:
Appendix F. Additional Supplied Modules

mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
  ALTER MAPPING FOR hword, hword_part, word
  WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
to_tsvector
-------------------
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
?column?
----------
t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
ts_headline
------------------------
 <b>Hôtel</b> de la Mer
(1 row)

F.44.3. Functions

The unaccent() function removes accents (diacritic signs) from a given string. Basically, it’s a wrapper around unaccent-type dictionaries, but it can be used outside normal text search contexts.

unaccent([dictionary regdictionary, ] string text) returns text

If the dictionary argument is omitted, the text search dictionary named unaccent and appearing in the same schema as the unaccent() function itself is used.

For example:

SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');

F.45. uuid-ossp

The uuid-ossp module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

F.45.1. uuid-ossp Functions

Table F-33 shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identi-
fied by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F-33. Functions for UUID Generation

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_generate_v1()</code></td>
<td>This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.</td>
</tr>
<tr>
<td><code>uuid_generate_v1mc()</code></td>
<td>This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.</td>
</tr>
<tr>
<td><code>uuid_generate_v3(namespace uuid, name text)</code></td>
<td>This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*()</code> functions shown in Table F-34. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <code>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</code> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</td>
</tr>
<tr>
<td><code>uuid_generate_v4()</code></td>
<td>This function generates a version 4 UUID, which is derived entirely from random numbers.</td>
</tr>
<tr>
<td><code>uuid_generate_v5(namespace uuid, name text)</code></td>
<td>This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.</td>
</tr>
</tbody>
</table>

Table F-34. Functions Returning UUID Constants

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uuid_nil()</code></td>
<td>A “nil” UUID constant, which does not occur as a real UUID.</td>
</tr>
<tr>
<td><code>uuid_ns_dns()</code></td>
<td>Constant designating the DNS namespace for UUIDs.</td>
</tr>
<tr>
<td><code>uuid_ns_url()</code></td>
<td>Constant designating the URL namespace for UUIDs.</td>
</tr>
</tbody>
</table>
F.45.2. Building `uuid-ossp`

Historically this module depended on the OSSP UUID library, which accounts for the module’s name. While the OSSP UUID library can still be found at http://www.ossp.org/pkg/lib/uuid/, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-ossp` can now be built without the OSSP library on some platforms. On FreeBSD, NetBSD, and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, OS X, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the e2fsprogs project (though on modern Linux it is considered part of util-linux-ng). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use e2fsprogs’ `libuuid`, or `--with-uuid=ossp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

**Note:** If you only need randomly-generated (version 4) UUIDs, consider using the `gen_random_uuid()` function from the `pgcrypto` module instead.

F.45.3. Author

Peter Eisentraut <peter_e@gmx.net>

F.46. `xml2`

The `xml2` module provides XPath querying and XSLT functionality.

F.46.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of PostgreSQL in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to `<pgsql-hackers@lists.postgresql.org>` so that the deficiency can be addressed.
F.46.2. Description of Functions

Table F-35 shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries. All arguments are of type text, so for brevity that is not shown.

Table F-35. Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_is_well_formed(document)</td>
<td>bool</td>
<td>This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: before PostgreSQL 8.2, this function was called xml_valid(). That is the wrong name since validity and well-formedness have different meanings in XML. The old name is still available, but is deprecated.)</td>
</tr>
<tr>
<td>xpath_string(document, query)</td>
<td>text</td>
<td>These functions evaluate the XPath query on the supplied document, and cast the result to the specified type.</td>
</tr>
<tr>
<td>xpath_number(document, query)</td>
<td>float4</td>
<td></td>
</tr>
<tr>
<td>xpath_bool(document, query)</td>
<td>bool</td>
<td></td>
</tr>
<tr>
<td>xpath_nodeset(document, query, toptag, itemtag)</td>
<td>text</td>
<td>This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like: <code>&lt;toptag&gt;</code> <code>&lt;itemtag&gt;Value 1 which could be an XML fragment &lt;/itemtag&gt;</code> <code>&lt;itemtag&gt;Value 2....&lt;/itemtag&gt;</code> <code>&lt;/toptag&gt;</code> If either toptag or itemtag is an empty string, the relevant tag is omitted.</td>
</tr>
<tr>
<td>xpath_nodeset(document, query)</td>
<td>text</td>
<td>Like xpath_nodeset(document, query, toptag, itemtag) but result omits both tags.</td>
</tr>
<tr>
<td>xpath_nodeset(document, query, itemtag)</td>
<td>text</td>
<td>Like xpath_nodeset(document, query, toptag, itemtag) but result omits toptag.</td>
</tr>
</tbody>
</table>
| xpath_list(document, query, separator)      | text        | This function returns multiple values separated by the specified separator, for example Value 1,Value 2,Value 3 if separator is ,.
**Function**

<table>
<thead>
<tr>
<th>Function</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath_list(document, query)</td>
<td>text</td>
<td>This is a wrapper for the above function that uses , as the separator.</td>
</tr>
</tbody>
</table>

**F.46.3. xpath_table**

`xpath_table(text key, text document, text relation, text xpaths, text criteria) returns setof record`

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in Table F-36.

**Table F-36. xpath_table Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)</td>
</tr>
<tr>
<td>document</td>
<td>the name of the field containing the XML document</td>
</tr>
<tr>
<td>relation</td>
<td>the name of the table or view containing the documents</td>
</tr>
<tr>
<td>xpaths</td>
<td>one or more XPath expressions, separated by</td>
</tr>
<tr>
<td>criteria</td>
<td>the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation</td>
</tr>
</tbody>
</table>

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table(‘article_id’,
    ‘article_xml’,
    ‘articles’,
    ‘/article/author*/article/pages*/article/title’,
    ‘date_entered > “2003-01-01” ’)
AS t(article_id integer, author text, page_count integer, title text);
```
Appendix F. Additional Supplied Modules

The AS clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be NULL.

Notice that this example defines the page_count result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use PostgreSQL input functions to transform it into an integer (or whatever type the AS clause requests). An error will result if it can’t do this — for example if the result is empty — so you may wish to just stick to text as the column type if you think your data has any problems.

The calling SELECT statement doesn’t necessarily have to be just SELECT * — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g. aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
    '/article/title|/article/author/@id',
    'xpath_string(article_xml, "/article/@date") > "2003-03-20" ')
AS t(article_id integer, title text, author_id integer),
tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.46.3.1. Multivalued Results

The xpath_table function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (  
    id int PRIMARY KEY,  
    xml text  
);

INSERT INTO test VALUES (1, '<doc num="C1">  
<line num="L1"> <a>1</a> <b>2</b> <c>3</c> </line>  
<line num="L2"> <a>11</a> <b>22</b> <c>33</c> </line>  
</doc>');  

INSERT INTO test VALUES (2, '<doc num="C2">  
<line num="L1"> <a>111</a> <b>222</b> <c>333</c> </line>  
<line num="L2"> <a>111</a> <b>222</b> <c>333</c> </line>  
</doc>');  

SELECT * FROM  
    xpath_table('id', 'xml', 'test',  
```
To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```sql
SELECT t.*, i.doc_num FROM
  xpath_table('id', 'xml', 'test', '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c', 'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id = t.id AND i.id = 1
ORDER BY doc_num, line_num;
```

<table>
<thead>
<tr>
<th>id</th>
<th>line_num</th>
<th>val1</th>
<th>val2</th>
<th>val3</th>
<th>doc_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>L1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>C1</td>
</tr>
<tr>
<td>1</td>
<td>L2</td>
<td>11</td>
<td>22</td>
<td>33</td>
<td>C1</td>
</tr>
</tbody>
</table>

(2 rows)

### F.46.4. XSLT Functions

The following functions are available if libxslt is installed:

#### F.46.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist) returns text`

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.
F.46.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as PostgreSQL.
Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding the modules that can be found in the contrib directory of the PostgreSQL distribution. See Appendix F for more information about the contrib section in general and server extensions and plug-ins found in contrib specifically.

This appendix covers utility programs found in contrib. Once installed, either from source or a packaging system, they are found in the bin directory of the PostgreSQL installation and can be used like any other program.

G.1. Client Applications

This section covers PostgreSQL client applications in contrib. They can be run from anywhere, independent of where the database server resides. See also Reference II, PostgreSQL Client Applications for information about client applications that part of the core PostgreSQL distribution.

oid2name

Name

oid2name — resolve OIDs and file nodes in a PostgreSQL data directory

Synopsis

oid2name [option...]

Description

oid2name is a utility program that helps administrators to examine the file structure used by PostgreSQL. To make use of it, you need to be familiar with the database file structure, which is described in Chapter 65.

Note: The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables’ filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.
Options

oid2name accepts the following command-line arguments:

- \texttt{-f filename}\n  show info for table with filenode \texttt{filename}\n- \texttt{-i}\n  include indexes and sequences in the listing\n- \texttt{-o oid}\n  show info for table with OID \texttt{oid}\n- \texttt{-q}\n  omit headers (useful for scripting)\n- \texttt{-s}\n  show tablespace OIDs\n- \texttt{-S}\n  include system objects (those in \texttt{information\_schema}, \texttt{pg\_toast} and \texttt{pg\_catalog} schemas)\n- \texttt{-t tablename\_pattern}\n  show info for table(s) matching \texttt{tablename\_pattern}\n- \texttt{-V}\n  \texttt{--version}\n  Print the \texttt{oid2name} version and exit.\n- \texttt{-x}\n  display more information about each object shown: tablespace name, schema name, and OID\n- \texttt{-?}\n  \texttt{--help}\n  Show help about \texttt{oid2name} command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

- \texttt{-d database}\n  database to connect to\n- \texttt{-H host}\n  database server’s host\n- \texttt{-p port}\n  database server’s port\n- \texttt{-U username}\n  user name to connect as
-P password

password (deprecated — putting this on the command line is a security hazard)

To display specific tables, select which tables to show by using -o, -f and/or -t. -o takes an OID, -f takes a filenode, and -t takes a table name (actually, it’s a LIKE pattern, so you can use things like foo%). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by -d.

If you don’t give any of -o, -f or -t, but do give -d, it will list all tables in the database named by -d. In this mode, the -S and -i options control what gets listed.

If you don’t give -d either, it will show a listing of database OIDs. Alternatively you can give -s to get a tablespace listing.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

$ # what’s in this database server, anyway?
$ oid2name

All databases:

<table>

Author

B. Palmer <bpalmer@crimelabs.net>
vacuumlo

Name
vacuumlo — remove orphaned large objects from a PostgreSQL database

Synopsis
vacuumlo [option...] dbname...

Description
vacuumlo is a simple utility program that will remove any "orphaned" large objects from a PostgreSQL database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any oid or lo data column of the database.

If you use this, you may also be interested in the lo_manage trigger in the lo module. lo_manage is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options
vacuumlo accepts the following command-line arguments:

-\l limit
Remove no more than limit large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding max_locks_per_transaction. Set the limit to zero if you want all removals done in a single transaction.

-n
Don’t remove anything, just show what would be done.

-v
Write a lot of progress messages.

-V
--version
Print the vacuumlo version and exit.

-?  --help
Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:
-h hostname
    Database server’s host.

-p port
    Database server’s port.

-U username
    User name to connect as.

-w
    --no-password
    Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a .pgpass file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W
    Force vacuumlo to prompt for a password before connecting to a database.
    This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

Notes
vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type oid or lo, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

G.2. Server Applications

This section covers PostgreSQL server-related applications in contrib. They are typically run on the host where the database server resides. See also Reference III, *PostgreSQL Server Applications* for information about server applications that part of the core PostgreSQL distribution.

**pg_standby**

**Name**

pg_standby — supports the creation of a PostgreSQL warm standby server

**Synopsis**

```
pg_standby [option...] archivelocation nextwalfile xlogfilepath [restartwalfile]
```

**Description**

pg_standby supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

pg_standby is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see Section 26.2).

To configure a standby server to use pg_standby, put this into its `recovery.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where `archiveDir` is the directory from which WAL segment files should be restored.

If `restartwalfile` is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from `archivelocation`. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the `archivelocation` is a transient staging area for this particular standby server, but *not* when the `archivelocation` is intended as a long-term WAL archive area.

pg_standby assumes that `archivelocation` is a directory readable by the server-owning user. If `restartwalfile` (or `-k`) is specified, the `archivelocation` directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

**Smart Failover**

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

**Fast Failover**

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast
failover, create a trigger file and write the word *fast* into it. *pg_standby* can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

**Options**

*pg_standby* accepts the following command-line arguments:

- `-c`
  
  Use *cp* or *copy* command to restore WAL files from archive. This is the only supported behavior so this option is useless.

- `-d`
  
  Print lots of debug logging output on *stderr*.

- `-k`
  
  Remove files from *archiveloop* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archiveloop*. This parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of PostgreSQL 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

- `-r maxretries`
  
  Set the maximum number of times to retry the *copy* command if it fails (default 3). After each failure, we wait for *sleeptime* * num_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

- `-s sleeptime`
  
  Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult Section 26.2 for discussion.

- `-t triggerfile`
  
  Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example /tmp/pgsql.trigger.5432.

- `-V`
  
  Print the *pg_standby* version and exit.

- `-w maxwaittime`
  
  Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult Section 26.2 for discussion.
-?
--help

Show help about pg_standby command line arguments, and exit.

Notes

pg_standby is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the %r macro, which is designed to let pg_standby know the last file it needs to keep. With PostgreSQL 8.2, the -k option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the recovery_end_command option. Without this option a leftover trigger file can be hazardous.

pg_standby is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs.

Examples

On Linux or Unix systems, you might use:

archive_command = 'cp $p .../archive/%f'
restore_command = 'pg_standby -d -s 2 -t /tmppgsql.trigger.5442 .../archive %f $p %r 2>>standby.log'
recovery_end_command = 'rm -f /tmppgsql.trigger.5442'

where the archive directory is physically located on the standby server, so that the archive_command is accessing it across NFS, but the files are local to the standby (enabling use of ln). This will:

- produce debugging output in standby.log
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called /tmppgsql.trigger.5442 appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

archive_command = 'copy $p ...\archive\%f'
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\archive %f $p %r 2>>standby.log'
recovery_end_command = 'del C:\pgsql.trigger.5442'

Note that backslashes need to be doubled in the archive_command, but not in the restore_command or recovery_end_command. This will:
• use the `copy` command to restore WAL files from archive
• produce debugging output in `standby.log`
• sleep for 5 seconds between checks for next WAL file availability
• stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
• remove the trigger file when recovery ends
• remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits `sleptime` seconds once it sees the proper file size. GNUWin32’s `cp` sets the file size only after the file copy is complete.
Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

Appendix H. External Projects

PostgreSQL is a complex software project, and managing the project is difficult. We have found that many enhancements to PostgreSQL can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base PostgreSQL distribution:

- libpq is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- ECPG is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in PostgreSQL itself.

All other language interfaces are external projects and are distributed separately. Table H-1 includes a list of some of these projects. Note that some of these packages might not be released under the same license as PostgreSQL. For more information on each language interface, including licensing terms, refer to its website and documentation.

H.2. Administration Tools

There are several administration tools available for PostgreSQL. The most popular is pgAdmin1, and there are several commercially available ones as well.

H.3. Procedural Languages

PostgreSQL includes several procedural languages with the base distribution: PL/pgSQL, PL/Tcl, PL/Perl, and PL/Python.

In addition, there are a number of procedural languages that are developed and maintained outside the core PostgreSQL distribution. Table H-2 lists some of these packages. Note that some of these projects might not be released under the same license as PostgreSQL. For more information on each procedural language, including licensing information, refer to its website and documentation.

H.4. Extensions

PostgreSQL is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The contrib/ directory shipped with the source code contains several extensions, which are described in Appendix F. Other extensions are developed independently, like PostGIS2. Even PostgreSQL replication solutions can be developed externally. For example, Slony-I3 is a popular master/standby replication solution that is developed independently from the core project.

2. http://postgis.net/
Appendix I. The Source Code Repository

The PostgreSQL source code is stored and managed using the Git version control system. A public mirror of the master repository is available; it is updated within a minute of any change to the master repository.

Our wiki, https://wiki.postgresql.org/wiki/Working_with_Git, has some discussion on working with Git.

Note that building PostgreSQL from the source repository requires reasonably up-to-date versions of bison, flex, and Perl. These tools are not needed to build from a distribution tarball, because the files that these tools are used to build are included in the tarball. Other tool requirements are the same as shown in Section 16.2.

I.1. Getting The Source via Git

With Git you will make a copy of the entire code repository on your local machine, so you will have access to all history and branches offline. This is the fastest and most flexible way to develop or test patches.

Git

1. You will need an installed version of Git, which you can get from https://git-scm.com. Many systems already have a recent version of Git installed by default, or available in their package distribution system.

2. To begin using the Git repository, make a clone of the official mirror:

   git clone https://git.postgresql.org/git/postgresql.git

   This will copy the full repository to your local machine, so it may take a while to complete, especially if you have a slow Internet connection. The files will be placed in a new subdirectory postgresql of your current directory.

   The Git mirror can also be reached via the Git protocol. Just change the URL prefix to git, as in:

   git clone git://git.postgresql.org/git/postgresql.git

3. Whenever you want to get the latest updates in the system, cd into the repository, and run:

   git fetch

Git can do a lot more things than just fetch the source. For more information, consult the Git man pages, or see the website at https://git-scm.com.
Appendix J. Documentation

PostgreSQL has four primary documentation formats:

- Plain text, for pre-installation information
- HTML, for on-line browsing and reference
- PDF or PostScript, for printing
- man pages, for quick reference.

Additionally, a number of plain-text README files can be found throughout the PostgreSQL source tree, documenting various implementation issues.

HTML documentation and man pages are part of a standard distribution and are installed by default. PDF and PostScript format documentation is available separately for download.

J.1. DocBook

The documentation sources are written in DocBook, which is a markup language superficially similar to HTML. Both of these languages are applications of the Standard Generalized Markup Language, SGML, which is essentially a language for describing other languages. In what follows, the terms DocBook and SGML are both used, but technically they are not interchangeable.

DocBook allows an author to specify the structure and content of a technical document without worrying about presentation details. A document style defines how that content is rendered into one of several final forms. DocBook is maintained by the OASIS group. The official DocBook site has good introductory and reference documentation and a complete O’Reilly book for your online reading pleasure. The NewbieDoc Docbook Guide is very helpful for beginners. The FreeBSD Documentation Project also uses DocBook and has some good information, including a number of style guidelines that might be worth considering.

J.2. Tool Sets

The following tools are used to process the documentation. Some might be optional, as noted.

DocBook DTD

This is the definition of DocBook itself. We currently use version 4.2; you cannot use later or earlier versions. You need the SGML variant of the DocBook DTD, but to build man pages you also need the XML variant of the same version.

ISO 8879 character entities

These are required by DocBook but are distributed separately because they are maintained by ISO.

DocBook DSSSL Stylesheets

These contain the processing instructions for converting the DocBook sources to other formats, such as HTML.

DocBook XSL Stylesheets

This is another stylesheet for converting DocBook to other formats. We currently use this to produce man pages and optionally HTMLHelp. You can also use this toolchain to produce HTML or PDF output, but official PostgreSQL releases use the DSSSL stylesheets for that.

The minimum required version is currently 1.74.0.

OpenJade

This is the base package of SGML processing. It contains an SGML parser, a DSSSL processor (that is, a program to convert SGML to other formats using DSSSL stylesheets), as well as a number of related tools. Jade is now being maintained by the OpenJade group, no longer by James Clark.

Libxml2 for xmllint

This library and the xmllint tool it contains are used for processing XML. Many developers will already have Libxml2 installed, because it is also used when building the PostgreSQL code. Note, however, that xmllint might need to be installed from a separate subpackage.

Libxslt for xsltproc

This is the processing tool to use with the XSLT stylesheets (like jade is the processing tool for DSSSL stylesheets).

JadeTeX

If you want to, you can also install JadeTeX to use TeX as a formatting backend for Jade. JadeTeX can create PostScript or PDF files (the latter with bookmarks).

However, the output from JadeTeX is inferior to what you get from the RTF backend. Particular problem areas are tables and various artifacts of vertical and horizontal spacing. Also, there is no opportunity to manually polish the results.

We have documented experience with several installation methods for the various tools that are needed to process the documentation. These will be described below. There might be some other packaged distributions for these tools. Please report package status to the documentation mailing list, and we will include that information here.

11. http://xmlsoft.org/XSLT/
J.2.1. Installation on Fedora, RHEL, and Derivatives

To install the required packages, use:

```
yum install docbook-dtds docbook-style-dsssl docbook-style-xsl libxslt openjade
```

J.2.2. Installation on FreeBSD

The FreeBSD Documentation Project is itself a heavy user of DocBook, so it comes as no surprise that there is a full set of “ports” of the documentation tools available on FreeBSD. The following ports need to be installed to build the documentation on FreeBSD.

- textproc/docbook-sgml
- textproc/docbook-xml
- textproc/docbook-xsl
- textproc/dsssl-docbook-modular
- textproc/libxslt
- textproc/openjade

A number of things from `/usr/ports/print (tex, jadetex)` might also be of interest.

More information about the FreeBSD documentation tools can be found in the FreeBSD Documentation Project’s instructions.\(^\text{13}\).

J.2.3. Debian Packages

There is a full set of packages of the documentation tools available for Debian GNU/Linux. To install, simply use:

```
apt-get install docbook docbook-dsssl docbook-xsl libxml2-utils openjade1.3 opensp xsltp
```

J.2.4. OS X

If you use MacPorts, the following will get you set up:

```
sudo port install docbook-dsssl docbook-sgml-4.2 docbook-xml-4.2 docbook-xsl libxslt openjade
```

J.2.5. Manual Installation from Source

The manual installation process of the DocBook tools is somewhat complex, so if you have pre-built packages available, use them. We describe here only a standard setup, with reasonably standard installation paths, and no “fancy” features. For details, you should study the documentation of the respective package, and read SGML introductory material.

J.2.5.1. Installing OpenJade

1. The installation of OpenJade offers a GNU-style
./configure; make; make install build process. Details can be found in the OpenJade source distribution. In a nutshell:

```
./configure --enable-default-catalog=/usr/local/share/sgml/catalog
make
make install
```

Be sure to remember where you put the “default catalog”; you will need it below. You can also leave it off, but then you will have to set the environment variable

SGML_CATALOG_FILES
to point to the file whenever you use jade later on. (This method is also an option if OpenJade is already installed and you want to install the rest of the toolchain locally.)

**Note:** Some users have reported encountering a segmentation fault using OpenJade 1.4devel to build the PDFs, with a message like:

```
openjade:./stylesheet.dsl:664:2:E: flow object not accepted by port; only display flow objects accepted
Downgrading to OpenJade 1.3 should get rid of this error.
```

2. Additionally, you should install the files dsssl.dtd, fot.dtd, style-sheet.dtd, and catalog from the dsssl directory somewhere, perhaps into /usr/local/share/sgml/dsssl. It’s probably easiest to copy the entire directory:

```
cp -R dsssl /usr/local/share/sgml
```

3. Finally, create the file /usr/local/share/sgml/catalog and add this line to it:

```
CATALOG "dsssl/catalog"
```

(This is a relative path reference to the file installed in step 2. Be sure to adjust it if you chose your installation layout differently.)

J.2.5.2. Installing the DocBook DTD Kit

1. Obtain the DocBook V4.2 distribution\(^{14}\).

2. Create the directory /usr/local/share/sgml/docbook-4.2 and change to it. (The exact location is irrelevant, but this one is reasonable within the layout we are following here.)

```
$ mkdir /usr/local/share/sgml/docbook-4.2
$ cd /usr/local/share/sgml/docbook-4.2
```

3. Unpack the archive:

```
$ unzip -a ...../docbook-4.2.zip
```

(The archive will unpack its files into the current directory.)

\(^{14}\) http://www.docbook.org/sgml/4.2/docbook-4.2.zip
4. Edit the file /usr/local/share/sgml/catalog (or whatever you told jade during installation) and put a line like this into it:

```
CATALOG "docbook-4.2/docbook.cat"
```

5. Download the ISO 8879 character entities archive\(^{15}\), unpack it, and put the files in the same directory you put the DocBook files in:

```
$ cd /usr/local/share/sgml/docbook-4.2
$ unzip ....../ISOEnts.zip
```

6. Run the following command in the directory with the DocBook and ISO files:

```
perl -pi -e 's/iso-(.*).gml/ISO\1/g' docbook.cat
```

(This fixes a mixup between the names used in the DocBook catalog file and the actual names of the ISO character entity files.)

### J.2.5.3. Installing the DocBook DSSSL Style Sheets

To install the style sheets, unzip and untar the distribution and move it to a suitable place, for example /usr/local/share/sgml. (The archive will automatically create a subdirectory.)

```
$ gunzip docbook-dsssl-1.xx.tar.gz
$ tar -C /usr/local/share/sgml -xf docbook-dsssl-1.xx.tar
```

The usual catalog entry in /usr/local/share/sgml/catalog can also be made:

```
CATALOG "docbook-dsssl-1.xx/catalog"
```

Because stylesheets change rather often, and it's sometimes beneficial to try out alternative versions, PostgreSQL doesn't use this catalog entry. See Section J.2.6 for information about how to select the stylesheets instead.

### J.2.5.4. Installing JadeTeX

To install and use JadeTeX, you will need a working installation of TeX and LaTeX2e, including the supported tools and graphics packages, Babel, AMS fonts and AMS-LaTeX, the PSNFSS extension and companion kit of “the 35 fonts”, the dvips program for generating PostScript, the macro packages fancyhdr, hyperref, minitoc, url and ot2enc. All of these can be found on your friendly neighborhood CTAN site\(^{16}\). The installation of the TeX base system is far beyond the scope of this introduction. Binary packages should be available for any system that can run TeX.

Before you can use JadeTeX with the PostgreSQL documentation sources, you will need to increase the size of TeX’s internal data structures. Details on this can be found in the JadeTeX installation instructions.

Once that is finished you can install JadeTeX:

```
$ gunzip jadetex-xxx.tar.gz
$ tar xf jadetex-xxx.tar
$ cd jadetex
$ make install
$ mktexlsr
```

---

The last two need to be done as root.

### J.2.6. Detection by `configure`

Before you can build the documentation you need to run the `configure` script as you would when building the PostgreSQL programs themselves. Check the output near the end of the run, it should look something like this:

```plaintext
checking for onsgmls... onsgmls
checking for openjade... openjade
checking for DocBook V4.2... yes
checking for DocBook stylesheets... /usr/share/sgml/docbook/stylesheet/dsssl/modular
checking for collateindex.pl... /usr/bin/collateindex.pl
checking for xsltproc... xsltproc
checking for osx... osx
```

If neither `onsgmls` nor `nsgmls` were found then some of the following tests will be skipped. `nsgmls` is part of the Jade package. You can pass the environment variables `JADE` and `NSGMLS` to `configure` to point to the programs if they are not found automatically. If “DocBook V4.2” was not found then you did not install the DocBook DTD kit in a place where Jade can find it, or you have not set up the catalog files correctly. See the installation hints above. The DocBook stylesheets are looked for in a number of relatively standard places, but if you have them some other place then you should set the environment variable `DOCBOOKSTYLE` to the location and rerun `configure` afterwards.

### J.3. Building The Documentation

Once you have everything set up, change to the directory `doc/src/sgml` and run one of the commands described in the following subsections to build the documentation. (Remember to use GNU make.)

#### J.3.1. HTML

To build the HTML version of the documentation:

```
doc/src/sgml$ make html
```

This is also the default target. The output appears in the subdirectory `html`.

To produce HTML documentation with the stylesheet used on postgresql.org instead of the default simple style use:

```
doc/src/sgml$ make STYLE=website html
```

To create a proper index, the build might process several identical stages. If you do not care about the index, and just want to proof-read the output, use `draft`:

```
doc/src/sgml$ make draft
```

---

17. [https://www.postgresql.org/docs/current](https://www.postgresql.org/docs/current)
To build the documentation as a single HTML page, use:

```
doc/src/sgml$ make postgres.html
```

### J.3.2. Manpages

We use the DocBook XSL stylesheets to convert DocBook `refentry` pages to *roff output suitable for man pages. The man pages are also distributed as a tar archive, similar to the HTML version. To create the man pages, use the commands:

```
cd doc/src/sgml
make man
```

### J.3.3. Print Output via JadeTeX

If you want to use JadeTeX to produce a printable rendition of the documentation, you can use one of the following commands:

- To generate PostScript via DVI in A4 format:

```
doc/src/sgml$ make postgres-A4.ps
```

In U.S. letter format:

```
doc/src/sgml$ make postgres-US.ps
```

- To make a PDF:

```
doc/src/sgml$ make postgres-A4.pdf
```

or:

```
doc/src/sgml$ make postgres-US.pdf
```

(Of course you can also make a PDF version from the PostScript, but if you generate PDF directly, it will have hyperlinks and other enhanced features.)

When using JadeTeX to build the PostgreSQL documentation, you will probably need to increase some of TeX’s internal parameters. These can be set in the file `texmf.cnf`. The following settings worked at the time of this writing:

```
hash_extra.jadetex = 200000
hash_extra.pdfjadetex = 200000
pool_size.jadetex = 2000000
pool_size.pdfjadetex = 2000000
string_vacancies.jadetex = 150000
string_vacancies.pdfjadetex = 150000
max_strings.jadetex = 300000
max_strings.pdfjadetex = 300000
save_size.jadetex = 15000
save_size.pdfjadetex = 15000
```
J.3.4. Overflow Text

Occasionally text is too wide for the printed margins, and in extreme cases, too wide for the printed page, e.g. non-wrapped text, wide tables. Overly wide text generates “Overfull hbox” messages in the TeX log output file, e.g. `postgres-US.log` or `postgres-A4.log`. There are 72 points in an inch so anything reported as over 72 points too wide will probably not fit on the printed page (assuming one inch margins). To find the SGML text causing the overflow, find the first page number mentioned above the overflow message, e.g. `[50 ###]` (page 50), and look at the page after that (e.g. page 51) in the PDF file to see the overflow text and adjust the SGML accordingly.

J.3.5. Print Output via RTF

You can also create a printable version of the PostgreSQL documentation by converting it to RTF and applying minor formatting corrections using an office suite. Depending on the capabilities of the particular office suite, you can then convert the documentation to PostScript or PDF. The procedure below illustrates this process using Applixware.

**Note:** It appears that current versions of the PostgreSQL documentation trigger some bug in or exceed the size limit of OpenJade. If the build process of the RTF version hangs for a long time and the output file still has size 0, then you might have hit that problem. (But keep in mind that a normal build takes 5 to 10 minutes, so don’t abort too soon.)

Applixware RTF Cleanup

OpenJade omits specifying a default style for body text. In the past, this undiagnosed problem led to a long process of table of contents generation. However, with great help from the Applixware folks the symptom was diagnosed and a workaround is available.

1. Generate the RTF version by typing:
   ```
   doc/src/sgml$ make postgres.rtf
   ```

2. Repair the RTF file to correctly specify all styles, in particular the default style. If the document contains `refentry` sections, one must also replace formatting hints which tie a preceding paragraph to the current paragraph, and instead tie the current paragraph to the following one. A utility, `fixrtf`, is available in `doc/src/sgml` to accomplish these repairs:
   ```
   doc/src/sgml$ ./fixrtf --refentry postgres.rtf
   ```

   The script adds `{s0 Normal;}` as the zeroth style in the document. According to Applixware, the RTF standard would prohibit adding an implicit zeroth style, though Microsoft Word happens to handle this case. For repairing `refentry` sections, the script replaces `\keepn` tags with `\keep`.

3. Open a new document in Applixware Words and then import the RTF file.

4. Generate a new table of contents (ToC) using Applixware.
   a. Select the existing ToC lines, from the beginning of the first character on the first line to the last character of the last line.
Appendix J. Documentation

b. Build a new ToC using Tools → Book Building → Create Table of Contents. Select the first three levels of headers for inclusion in the ToC. This will replace the existing lines imported in the RTF with a native Applixware ToC.

c. Adjust the ToC formatting by using Format → Style, selecting each of the three ToC styles, and adjusting the indents for First and Left. Use the following values:

<table>
<thead>
<tr>
<th>Style</th>
<th>First Indent (inches)</th>
<th>Left Indent (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOC-Heading 1</td>
<td>0.4</td>
<td>0.4</td>
</tr>
<tr>
<td>TOC-Heading 2</td>
<td>0.8</td>
<td>0.8</td>
</tr>
<tr>
<td>TOC-Heading 3</td>
<td>1.2</td>
<td>1.2</td>
</tr>
</tbody>
</table>

5. Work through the document to:
   - Adjust page breaks.
   - Adjust table column widths.

6. Replace the right-justified page numbers in the Examples and Figures portions of the ToC with correct values. This only takes a few minutes.

7. Delete the index section from the document if it is empty.

8. Regenerate and adjust the table of contents.
   a. Select the ToC field.
   b. Select Tools → Book Building → Create Table of Contents.
   c. Unbind the ToC by selecting Tools → Field Editing → Unprotect.
   d. Delete the first line in the ToC, which is an entry for the ToC itself.

9. Save the document as native Applixware Words format to allow easier last minute editing later.

10. “Print” the document to a file in PostScript format.

J.3.6. Plain Text Files

The installation instructions are also distributed as plain text, in case they are needed in a situation where better reading tools are not available. The INSTALL file corresponds to Chapter 16, with some minor changes to account for the different context. To recreate the file, change to the directory doc/src/sgml and enter make INSTALL.

In the past, the release notes and regression testing instructions were also distributed as plain text, but this practice has been discontinued.

J.3.7. Syntax Check

Building the documentation can take very long. But there is a method to just check the correct syntax of the documentation files, which only takes a few seconds:

doc/src/sgml$ make check
J.4. Documentation Authoring

SGML and DocBook do not suffer from an oversupply of open-source authoring tools. The most common tool set is the Emacs/XEmacs editor with appropriate editing mode. On some systems these tools are provided in a typical full installation.

J.4.1. Emacs/PSGML

PSGML is the most common and most powerful mode for editing SGML documents. When properly configured, it will allow you to use Emacs to insert tags and check markup consistency. You could use it for HTML as well. Check the PSGML web site for downloads, installation instructions, and detailed documentation.

There is one important thing to note with PSGML: its author assumed that your main SGML DTD directory would be /usr/local/lib/sgml. If, as in the examples in this chapter, you use /usr/local/share/sgml, you have to compensate for this, either by setting SGML_CATALOG_FILES environment variable, or you can customize your PSGML installation (its manual tells you how).

Put the following in your ~/.emacs environment file (adjusting the path names to be appropriate for your system):

```elisp
; ********** for SGML mode (psgml)
(setq sgml-omittag t)
(setq sgml-shorttag t)
(setq sgml-minimize-attributes nil)
(setq sgml-always-quote-attributes t)
(setq sgml-indent-step 1)
(setq sgml-indent-data t)
(setq sgml-parent-document nil)
(setq sgml-exposed-tags nil)
(setq sgml-catalog-files ’(/usr/local/share/sgml/catalog'))

;autoload ’sgml-mode "psgml" 
Major mode to edit SGML files." t )
```

and in the same file add an entry for SGML into the (existing) definition for auto-mode-alist:

```elisp
(setq
  auto-mode-alist
  '(("\.sgml$" . sgml-mode)
    ))
```

You might find that when using PSGML, a comfortable way of working with these separate files of book parts is to insert a proper DOCTYPE declaration while you’re editing them. If you are working on this source, for instance, it is an appendix chapter, so you would specify the document as an “appendix” instance of a DocBook document by making the first line look like this:

This means that anything and everything that reads SGML will get it right, and I can verify the document with `nsgmls -s docguide.sgml`. (But you need to take out that line before building the entire documentation set.)

### J.4.2. Other Emacs Modes

GNU Emacs ships with a different SGML mode, which is not quite as powerful as PSGML, but it’s less confusing and lighter weight. Also, it offers syntax highlighting (font lock), which can be very helpful. `src/tools/editors/emacs.samples` contains sample settings for this mode.

Norm Walsh offers a major mode\(^19\) specifically for DocBook which also has font-lock and a number of features to reduce typing.

### J.5. Style Guide

#### J.5.1. Reference Pages

Reference pages should follow a standard layout. This allows users to find the desired information more quickly, and it also encourages writers to document all relevant aspects of a command. Consistency is not only desired among PostgreSQL reference pages, but also with reference pages provided by the operating system and other packages. Hence the following guidelines have been developed. They are for the most part consistent with similar guidelines established by various operating systems.

Reference pages that describe executable commands should contain the following sections, in this order. Sections that do not apply can be omitted. Additional top-level sections should only be used in special circumstances; often that information belongs in the “Usage” section.

- **Name**
  
  This section is generated automatically. It contains the command name and a half-sentence summary of its functionality.

- **Synopsis**
  
  This section contains the syntax diagram of the command. The synopsis should normally not list each command-line option; that is done below. Instead, list the major components of the command line, such as where input and output files go.

- **Description**
  
  Several paragraphs explaining what the command does.

- **Options**
  
  A list describing each command-line option. If there are a lot of options, subsections can be used.

- **Exit Status**
  
  If the program uses 0 for success and non-zero for failure, then you do not need to document it. If there is a meaning behind the different non-zero exit codes, list them here.

\(^19\) http://nwalsh.com/emacs/docbookide/index.html
Appendix J. Documentation

Usage

Describe any sublanguage or run-time interface of the program. If the program is not interactive, this section can usually be omitted. Otherwise, this section is a catch-all for describing run-time features. Use subsections if appropriate.

Environment

List all environment variables that the program might use. Try to be complete; even seemingly trivial variables like SHELL might be of interest to the user.

Files

List any files that the program might access implicitly. That is, do not list input and output files that were specified on the command line, but list configuration files, etc.

Diagnostics

Explain any unusual output that the program might create. Refrain from listing every possible error message. This is a lot of work and has little use in practice. But if, say, the error messages have a standard format that the user can parse, this would be the place to explain it.

Notes

Anything that doesn’t fit elsewhere, but in particular bugs, implementation flaws, security considerations, compatibility issues.

Examples

Examples

History

If there were some major milestones in the history of the program, they might be listed here. Usually, this section can be omitted.

Author

Author (only used in the contrib section)

See Also

Cross-references, listed in the following order: other PostgreSQL command reference pages, PostgreSQL SQL command reference pages, citation of PostgreSQL manuals, other reference pages (e.g., operating system, other packages), other documentation. Items in the same group are listed alphabetically.

Reference pages describing SQL commands should contain the following sections: Name, Synopsis, Description, Parameters, Outputs, Notes, Examples, Compatibility, History, See Also. The Parameters section is like the Options section, but there is more freedom about which clauses of the command can be listed. The Outputs section is only needed if the command returns something other than a default command-completion tag. The Compatibility section should explain to what extent this command conforms to the SQL standard(s), or to which other database system it is compatible. The See Also section of SQL commands should list SQL commands before cross-references to programs.
Appendix K. Acronyms

This is a list of acronyms commonly used in the PostgreSQL documentation and in discussions about PostgreSQL.

ANSI
   American National Standards Institute\(^1\)
API
   Application Programming Interface\(^2\)
ASCII
   American Standard Code for Information Interchange\(^3\)
BKI
   Backend Interface
CA
   Certificate Authority\(^4\)
CIDR
   Classless Inter-Domain Routing\(^5\)
CPAN
   Comprehensive Perl Archive Network\(^6\)
CRL
   Certificate Revocation List\(^7\)
CSV
   Comma Separated Values\(^8\)
CTE
   Common Table Expression
CVE
   Common Vulnerabilities and Exposures\(^9\)
DBA
   Database Administrator\(^10\)

Appendix K. Acronyms

DBI
Database Interface (Perl)\(^1\)

DBMS
Database Management System\(^2\)

DDL
Data Definition Language\(^3\), SQL commands such as `CREATE TABLE`, `ALTER USER`

DML
Data Manipulation Language\(^4\), SQL commands such as `INSERT`, `UPDATE`, `DELETE`

DST
Daylight Saving Time\(^5\)

ECPG
Embedded C for PostgreSQL

ESQL
Embedded SQL\(^6\)

FAQ
Frequently Asked Questions\(^7\)

FSM
Free Space Map

GEQO
Genetic Query Optimizer

GIN
Generalized Inverted Index

GiST
Generalized Search Tree

Git
Git\(^8\)

GMT
Greenwich Mean Time\(^9\)

GSSAPI
Generic Security Services Application Programming Interface\(^10\)

GUC
Grand Unified Configuration, the PostgreSQL subsystem that handles server configuration

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department web site¹.

SQL Reference Books

PostgreSQL-specific Documentation

Discusses SQL history and syntax, and describes the addition of INTERSECT and EXCEPT constructs into PostgreSQL. Prepared as a Master’s Thesis with the support of O. Univ. Prof. Dr. Georg Gottlob and Univ. Ass. Mag. Katrin Seyr at Vienna University of Technology.

Zelaine Fong, *The design and implementation of the POSTGRES query optimizer* ², University of California, Berkeley, Computer Science Department.
